When estimating roughly what current radiators are to be wound for, for a given space, I generally assume that 500 watts will be necessary per 1,000 cubic feet of space, in the coldest weather. This, of course, is only a very rough guide, and in every case the general conditions must be taken into consideration. In my office in the city, which has a capacity of 2,000 cubic feet, with one outside wall almost entirely consisting of window space, I rarely use a larger radiator than one absorbing 600 watts. In very sharp weather I have found it necessary to put two of these on for the earlier part of the morning, and sometimes on Mondays, after a continued frost extending over Saturday and Sunday. In this instance it will be seen that a less quantity is required than 500 watts per 1,000 cubic feet of space. In the case of a building with several thin outside walls, and other unfavorable conditions, probably more than the 500 watts would have to be provided for.

With radiators consuming this amount of energy you will appreciate that electric heating is not likely to receive much support when such charges as 8d. per unit are made. At the beginning of last year I was requested by an architect to fit nine radiators in a spacious office in the city. The firm was a wealthy one, and expense was not considered an important matter owing to the convenience of the electric radiators. I pointed out before the order was placed that the cost of current would probably be very high; but, notwithstanding my warning, it was decided to have the radiators fixed. After they had been running for three or four months I was informed that the cost was so excessive that their use would have to be discontinued. With one or two small exceptions these are the only radiators ever installed in the city of London, and, while the prices are maintained at the present figure, little development is likely to take place; and yet the city is an almost ideal place for the use of electric radiators, owing to the fact that the bulk of the offices close at an early hour, and that the occupiers are willing to pay a good price for so convenient and sanitary means of heating as electric radiators provide.

Experience shows that even at so high a figure as 3d. or 4d. there is considerable demand for electric radiators, and this is not surprising when one considers that the heat produced is of exactly the quality that one could desire. It is not sufficiently high to deprive the air of its moisture. There are no products of combustion to vitiate the atmosphere, and the radiators are turned on and off with the same ease as the electric light.

I cannot now make detailed mention of the smaller heating appliances, but I think that their employment is one worthy of some consideration by supply companies. If they are at all largely adopted, they would be of value in increasing the day load, and it is likely that they would be employed at times when the cooking apparatus would not be in use. Take, for instance, the electric kettle. Each kettle takes from 300 to 500 watts, and they are mainly used for preparing tea in the afternoon. It is conceivable that if used in large numbers they would help to fill up the somewhat awkward dip in the curve occurring about three or four o'clock in the afternoon after the hot cupboard and plate had gone out of use.

In conclusion, I will ask you to be as lenient as possible when passing judgment upon this paper. I am well aware that I have been guilty of considerable temerity in venturing to read a paper upon a subject about which there is so little practical knowledge. My excuse for doing so is that I believe there is a reasonable probability of considerable development in this direction in the near future, and I hope that the figures which I have placed before you may help electrical engineers and others interested to understand better the lines that this branch of electrical engineering lies upon them.

AUXILIARY CARS IN STORAGE BATTERY TRACTION.—SPECIAL CAR VIRGINIA.

Electrical Engineering at Columbia University.

The new buildings of Columbia University, New York, are located at One-hundred-and-sixteenth street, between the boulevard and Amsterdam avenue, on the highest part of Morningside Heights, midway between Grant's tomb and the new Episcopal cathedral, commanding a view of the Hudson on the west and the Harlem River on the east. Thus situated, the university secures the manifold advantages of metropolitan life, and at the same time it is sufficiently removed from the hurry and noise of the city to preserve the collegiate atmosphere. This effect is still further increased by the fact that the grounds between the buildings form a plateau about 20 feet above the level of the grounds and streets outside of the group of buildings. By this arrangement great economy in space is secured, since it gives two more floors to each of the buildings situated around the edge of the plateau, the basements and sub-basements being above the level of the surrounding grounds. The raised level between the buildings also enables tunnels to be constructed which connect the various buildings with the central power plant of the university. These tunnels afford connection for steam and gas service

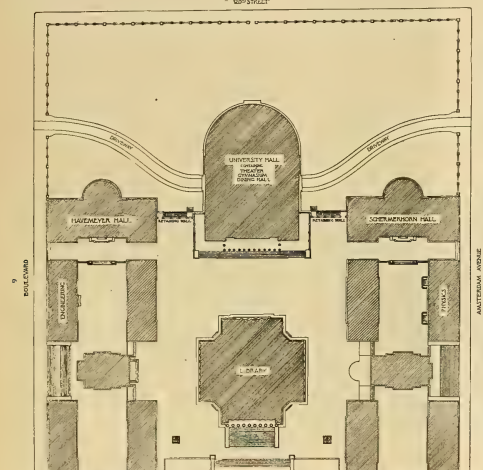

Fig. 1. Plan of New Buildings and Grounds.

Ninth and Tenth avenues, where it is well provided with buildings and equipment. All the other departments of the university, including Barnard College and the Teachers' College, which are affiliated with it, have removed to the new site.

The engineering building, a view of which, with its annex, is shown in Fig. 2, contains the departments of electrical, mechanical, civil and mining engineering. Havemeyer Hall, the chemistry building, is the home of one of the largest and best equipped chemical schools in the world, having been designed by Professor Charles F. Chandler and the officers of his department after a careful study of the principal colleges and technical schools in this country and abroad. The department of architecture is temporarily housed in the chemistry building, which has more than sufficient space for present needs. Schermerhorn Hall, the natural science building, contains the departments of geology, mineralogy, biology, etc., and their extensive collections. The physics building, which also accommodates the departments of mechanics and astronomy, is designed and equipped according to the modern methods for teaching and investigating physical science.

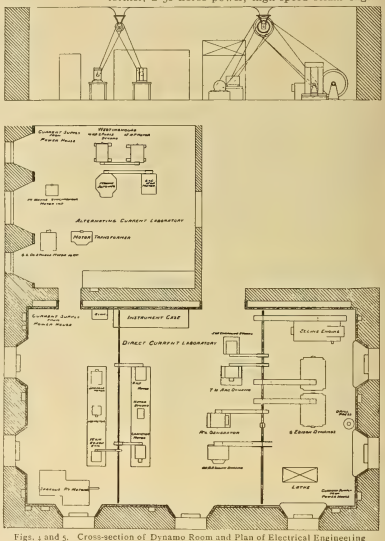
It is a striking fact, characteristic of modern tendencies, that all four of the new buildings, besides the library and university buildings, which are used for general purposes, are devoted entirely to science; and three of them are especially important in their relation to electrical engineering. Hence the course in electrical engineering at Columbia, which has already gained for itself a prominent position in electrical education in this country, has been materially benefited by the removal of the university to its new site. The principal improvements consist in a considerable extension of space and equipment in the electrical engineering laboratories, as well as in those devoted to mechanical engineering, physics and chemistry.

The regular four-years' course, leading to the degree of electrical engineer, is designed for the education of professional electrical engineers who intend to devote themselves to the practice of this profession, either as teachers in colleges and scientific schools, or as engineers, managers or experts in manufacturing or other industrial enterprises.

The course of instruction includes not only all important branches of theoretical and applied electricity, but also the other collateral sciences, which have been found by experience to be required by the electrical engineer, such as mathematics, physics, chemistry, drawing, analytical mechanics, mechanical engineering, including a thorough course in steam and other engines, as well as transmissive machinery and shopwork. General engineering, including construction in masonry, iron, steel and wood also forms parts of the course.

Hence the graduate in electrical engineering is provided not only with a thorough knowledge of the principles and practice of electricity, but also with such a broad and liberal education in the allied sciences as will prepare him for every demand that is likely to be made upon him in after life in connection with his profession, and will also enable him to become an investigator. The instruction is by lecture, recitation, laboratory, workshop and drawing-room practice, with periodical examinations. Special attention is given to new methods and forms of apparatus in order that the student may be brought fully abreast of the rapid progress of electrical science and practice. Frequent visits are made to the numerous electrical factories, stations and other establishments in and about New York.

The offices, laboratories, lecture and other rooms of the electrical engineering department are in the south end of the engineering building. In the sub-basement are located the storage battery and photometer rooms. The former contains a battery of 70 cells, to be used for efficiency and output tests and also as a source of steady potential and current. The photometer room is equipped with all necessary apparatus for determining the candle power of arc and incandescent lamps as well as other sources of light. In the basement are situated the two machine laboratories, the larger containing the direct-current machinery, while the smaller accommodates the alternating-current apparatus. These are shown in cross-section and plan in Figs. 4 and 3. In the former, a 50 horse power, high-speed steam engine



Figs. 4 and 5. Cross-section of Dynamo Room and Plan of Electrical Engineering Laboratory.

and the electrical conductors as well as the cartage of coal, ashes and supplies.

In this way these important practical matters are very conveniently carried on below ground as far as the college is concerned, but at the same time above the street level. Each building is provided with an elevator, chiefly used for carrying apparatus and supplies to and from the laboratories, lecture rooms and museums. Thus it is an easy matter to transport even heavy apparatus from any room in the university to any other room. To still further facilitate this service the door sills are entirely omitted in most of the rooms, so that a truck can be run about the buildings without jarring that which it carries, enabling apparatus to be arranged in the laboratory for use in the lecture rooms.

The location of the buildings at the new site are shown in the general plan, Fig. 1, the magnificent library presented by President Low being the central one and easily accessible from all the others. Only these buildings designated by names are already erected.

University Hall is the other general building, containing the power plant, gymnasium, academic theater, etc. There are also four new buildings respectively devoted to engineering, chemistry, natural science and physics. Two old buildings will be used for the present by the departments of ancient and modern languages and mathematics.

The schools of law, political science and philosophy are located in the library building, bringing them within convenient reach of the books upon which are especially dependent. The medical school will remain at Forty-ninth street, between

On the first floor, a plan of which is shown in Fig. 3, are situated the smaller lecture room (seating 70), ordinarily used for class work, and the larger lecture room (seating 150) for combined classes. In the chemical building, immediately adjoining, a still larger lecture room (seating 350) is available for meetings and public lectures. All of these rooms are provided with an ample supply of electrical energy of different forms, as well as gas, water and other facilities to enable experimental demonstrations to be conveniently and effectively performed. For example, dynamos, motors and other apparatus of practical size are shown in actual operation to illustrate the lectures, this being made a special feature of the instruction.

The museum contains cases for the collection of apparatus, models, materials, etc., relating to electrical engineering. This museum adjoins the

FIG. 2. ELECTRICAL ENGINEERING AT COLUMBIA UNIVERSITY.—ENGINEERING BUILDING.

lecture rooms, so that its contents can be conveniently used for illustration.

On the third floor are located the large instrumental laboratory, the research room and the studies of the officers. The laboratory contains a number of tables on which the instruments are permanently set up ready for use. These include various forms of galvanometers, ampere balances, standard cells and resistances; apparatus for measuring inductance, magnetic permeability, hysteresis and leakage; laboratory standard volt and amperemeters; telegraph, telephone and electric-signaling systems; thermo-electric and electrical heating devices; Röntgen-ray apparatus. The research room is used for special post-graduate and thesis work, and is fitted up according to the lines of investigation that are being followed.

A most important facility is the large and reliable supply of electrical current which is afforded by the central power plant of the university. This consists of boilers having an aggregate capacity of 2,000 horse power, two low-speed engines directly connected to two dynamos of 275 horse power each and two high-speed engines directly connected to two dynamos of 100 horse power each. This electrical generating plant, having a total capacity of 750 horse power, and illustrating the latest practice in electrical engineering, furnishes current for electric lighting and for driving the motors and fans used in ventilating all the buildings. Special conductors are also laid to convey to all the laboratories as well as lecture rooms of the electrical engineering department an ample supply of current for experimental work.

The physical laboratories and lecture rooms occupy four floors of the physics building on the eastern side of the university grounds. The building is supplied with all ordinary conveniences, including electricity for power and light, compressed air and steam. There is a vertical shaft 95 feet high with iron ladders and water outlet at every 10 feet. In the subbasement a constant-temperature room is placed 12 feet below the surface of the ground. A platform on the roof is available for meteorological observations, an instrument room being directly below. There are two lecture rooms, a library, an apparatus room and laboratories of various kinds.

The general elementary laboratory includes in its equipment linear and circular dividing engines of various designs. For measurement of mass there are provided balances with weights, specific-gravity apparatus, hydrometers, aerometers, and the various forms of vapor-density apparatus. Standard barometers, pendulums and apparatus for studying elasticity are provided, also apparatus for the study of sound.

The manometers and apparatus for their calibration and determination of zero and boiling points are supplied also apparatus for determination of coefficient of expansion, for latent and specific heat and calorimetry.

The optical room are furnished with a telescope of different designs, spectroscopes, telescopes, microscopes, sets of lenses, prisms and gratings, optical benches, photometers and apparatus for colorimetry, polarized light and spectroscopy.

In the rooms devoted to electricity are galvanometers of various patterns, high and low resistance, ballistic and damped; electrometers, magnetometers, standard cells, resistance, rheostats and bridges of all types; condensers, batteries, keys, arc and incandescent lamps, amperemeters and voltmeters.

THE MECHANICAL ENGINEERING DEPARTMENT.

The mechanical engineering department is located in the engineering building and in the annex, the space and equipment provided for it being greatly increased at the new site. This improvement is made not only on account of the importance of this branch in the electrical, civil and mining engineering courses, but also because regular courses in mechanical engineering have now been opened at Columbia for the first time, the space at the old site not having been adequate for the purpose. The department has the following equipment:

The woodworking and machine shops are located in the Teachers' College, One-hundred-and-twentieth street. For woodworking there are carpenters' benches with their kits of tools, speed lathes, sawbenches and planers. For forge and blacksmith work there are forges with anvils and tools, a Bradley hammer and a Billings & Spencer drop-press. For metal-working there are engine lathes with swing from 12 inches to 20 inches, planers, shapers, drill-presses, a universal milling machine, universal grinding machines and a Jones & Sampson turret lathe.

The testing laboratory is equipped with high-

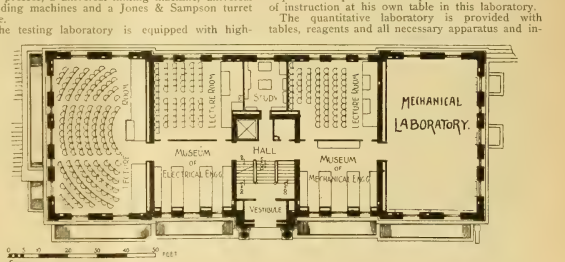


FIG. 3. ELECTRICAL ENGINEERING AT COLUMBIA UNIVERSITY. FIRST FLOOR ENGINEERING BUILDING

grade testing machines for tensile, transverse, torsion and compression tests. Their designs are of diverse types to give wide experience in handling and they are fitted with the best and newest appliances for observing and recording deformations of test pieces. The Emery testing machine, of 150,000 pounds capacity, is used as a standard of reference.

The mechanical engineering laboratory is well supplied with dynamometers of transmission and absorption types, with oil-testing appliances, speed recorders, tachometers, weighing and measuring apparatus, anemometers, gauge testers and the like, and representative machines and mechanisms for calibration and tests of efficiency.

The steam engineering and motive power laboratory has an extensive series of indicators, with appliances for calibrating and standardizing them, test-gauges, thermometers, calorimeters, pyrometers and apparatus for boiler and engine tests. A triple-expansion steam engine of the Reynolds-Allis-Corliss design is arranged to work on experimental steam engine by making it a three-stage air compressor when operated, and having all facilities for the accurate measurement of efficiencies. A full line of boiler-feed injectors is mounted for display and experiment. Steam engines of various other types, steam pumps, a 10 horse power De Laval steam turbine, hot-air and gas engines are at hand, and surface-condensing appliances as well. The department has also a cross-compound two-stage air compressor, the cross-compound steam end of which, with reheater, combined with the cross-compound air end with inter-cooler, makes a most complete example of applications of thermo-dynamic theory to practice. This laboratory is known as the Allis Laboratory, in memory of the late Edward P. Allis.

The hydraulic motor laboratory contains tanks, weir-notch equipment, gauges, current meters, water meters and motors for test and experiment. Constant pressure is secured by air pressure upon the water in a closed tank, thus doing away with a stand-pipe. For heavier pressures, above 100 pounds per square inch, an adjustable accumulator is used. Pumps of large capacity give the necessary quantity of water for orifice tests and other drill in hydraulic engineering. The equipment of this laboratory is presented as a gift to the university as a memorial of the late Henry R. Worthington of New York city.

The drawing academies are particularly well lighted and of large extent, and are fitted with the best forms of drawing tables and furniture, as well as extensive collections of patterns, models and illustrative drawings, blue prints, photographs and prints which are useful as copies and for training in design. Sectional models of actual machines and structural material are abundant, and for the study of projection, stone-cutting and warped surfaces there is a set of the Ollivier models, in which the elements of surfaces are represented by tense threads. In connection with the drawing academy is a room for blue printing and other solar work, and a photographic dark room.

The cabinets, or museum collections of mechanical engineering, exhibit models of mechanical movements, mechanisms and gearing, also material which has failed in service and under test. Specimens of apparatus and materials for practice are also included.

The chemical department occupies Havemeyer Hall, which is located at the northwestern corner of the group of buildings. It contains several chemical lecture rooms, fully supplied with apparatus and instruments and all modern facilities for the experimental illustration of the different lecture courses.

The museum of general inorganic and organic chemistry and of the chemical arts contains the elements and all their more important compounds, representative collections of specimens of all classes of compounds, materials and products, together with models, pictures and diagrams.

The qualitative laboratory is provided with tables, reagents, and all the necessary facilities to enable each student to become familiar with the reactions of the different metals and salts. The student is required to repeat all the experiments of the course of instruction at his own table in this laboratory.

The quantitative laboratory is provided with tables, reagents and all necessary apparatus and instruments to enable the student to actually execute quantitative analyses.

There is also a laboratory specially fitted up for electro-chemical work. The theoretical as well as practical branches of electrical engineering are taught by Professors F. B. Crocker and M. I. Pupin and Messrs. G. F. Sever, W. H. Freedman and S. G. P. Townsend.

BOOK TABLE.

ELEKTRISCHE LICHT UND KRAFT ANLAGEN ("Electric Light and Power Plants"). By Dr. Ludwig Fischer. Wiesbaden: 1898. Price, $1.65.

This is a volume of 317 pages, with 165 large half-tone illustrations. The author is the chief engineer of the Central Bureau (Hamburg) of the Export Union of German Electrical Manufacturers. The pictures form the principal feature, and many continental installations are illustrated. The book gives the results of European practice in compact and convenient form.

Western Electrician.

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO.

TELEPHONE, MAIN 1746.

EASTERN OFFICE: 108 TIMES BUILDING, NEW YORK.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING—THE WESTERN ELECTRICIAN — **the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

It is gratifying to receive assurances of appreciation such as those which have come from the independent telephone interests in all parts of the country since the appearance of the special number of the Western Electrician on February 26th, directing attention to the remarkable advancement already made in that field. Those engaged in that department are especially pleased with the excellent showing made on that occasion, but interest in the movement is not confined to those actively engaged in the independent field. Those who are even now associated with the Bell interests realize that a wider field of usefulness and a greater opportunity for personal advancement are presented in the independent movement. The electrical fraternity generally, outside the ranks of the telephone workers, encourages the opposition companies for similar reasons, and the public, which is vitally interested in the success of the independent movement, welcomes every development that contributes to its success, as it is by this means alone that permanent relief can be obtained from high prices in telephone service.

In view of the extent and diversity of the interests affected by the independent telephone movement, it is not surprising that the "Independent Telephone Number" of the Western Electrician should have proved such a popular publication. The new department devoted to this industry, which will here after be a feature of this journal, will each week contain the latest information obtainable, and, as its name implies, it will fairly represent the "Development of the Telephone Field."

The snow-fighting apparatus and special car of the Chicago Electric Traction company, described elsewhere in this issue, are interesting because of the storage-battery application. It is to be noted that thus far the storage-battery line has met every emergency of light, level railroading with success.

Opposition to the Bell interests has resulted in the introduction of the Brush telephone bill in the New York Legislature. The measure has been before that body in former years, but has never survived the ordeal of the committee. It is intended to restrict the local companies throughout the Empire state in their charges for service, but it is provided that these properties shall be enabled to earn 10 per cent. before the act shall apply to them. The chief objection to the measure on the part of the Bell companies, aside from the fact that those corporations resent interference and governmental supervision of their business, is that the actual cash investment shall form the basis upon which the percentage of profits shall be based. The valuation of the owners of the Bell exchanges upon the property will not be accepted. Other corporative influence is being exerted in behalf of the Bell exchanges in this struggle, and it is hardly possible that the bill shall be passed, although there is a formidable movement on foot against the Bell interests throughout New York.

At the hearing granted to the committee last week the friends of the bill presented petitions and arguments showing that there was a growing demand for relief throughout the state. The Bell companies will have an opportunity to present their defense before the measure is finally acted upon.

A study of the extensive use of natural water powers throughout Switzerland for the operation of machinery employed in the generation of electric current leads a contemporary to observe that a lesson is contained in this practice for Americans. In Switzerland, it is explained, there are many small streams, furnishing only a few cubic feet of water per second, which are tapped several hundred feet above the point where a power house can be conveniently built, and a cheap pipe line directs this energy upon the buckets of a Pelton impulse wheel or a Girard turbine. This power is largely used for the electric operation of mountain-climbing railways, which have grown so popular among visitors. While it is true that there is not the demand in this country for mountain-climbing roads that exists in the favored land of tourists, there is no reason why many minor streams should not be used in other ways. Many such sources of power in mountainous regions are not too far from points of utilization to be neglected, and it is contended that instead of searching for enormous water rights and organizing great development companies, some time and energy might well be spent in harnessing the mountain streams of America and setting them to work in the same effective manner as has been done with those of Switzerland. The suggestion is worthy of consideration.

Discussing the obstacles that have been overcome by American railroads during the last few years, the New York Sun calls attention to one important factor that will have to be taken into consideration in all future plans for steam railroading—the competition of the electric railway. It is pointed out that the development of the trolley system of traction has assured closer and cheaper connection between towns on the lines of railroad connection, and consequently the important and profitable item of local passenger traffic has been cut into severely. This is explained by the fact that electric lines are cheaply constructed, the roadbed costing little, and expensive locomotives and cars not being required. There is no burdensome transportation of fuel, no expenditure for terminals or stations, and practically no expenses for track walking or signaling. Many towns, more especially in the Middle and New England states, were built up by their proximity to a railroad, but during the last few years the passenger traffic between such towns has been diverted to a considerable extent from the steam to the electric railroads established to connect them; but the losses of the steam railroads have been made up by more progressive and economical operations. Incidentally, it is remarked that the government expended for mail service by electric and cable lines last year $325,000. The extension of electric lines in this manner is not confined to the New England and Middle states by any means. In Illinois, Minnesota, Ohio and Wisconsin there has been considerable development along this line, but it is expected that the plans now under consideration by several large steam railroads furnishing suburban traffic to Chicago will completely overshadow all that has heretofore been done in this department.

The tendency to place additional powers in the hands of the government, whether city, state or national, and incidentally to create lucrative offices for the friends of those who secure the passage of measures providing for these innovations, has reached a point where the subject is demanding public consideration. Among the bills of this kind introduced during the present session of the New York Legislature is one providing for an examining Board of Electricians "to examine and license" those having to do with electricity in any form, and requiring the payment of an annual fee of $25 for such certificate. The state of New York is already groaning under several commissions and boards which might be abolished without impairing public comfort or convenience. However, if the proposed board lived up to the requirements of the bill under which it is to be established the members would find plenty to do, although it is not equally certain that the electrical profession would be benefited. While it is true that the number of electricians in the state is comparatively small if the title be applied only to such as are proficient in the art, it is also a fact, as has been pointed out, that under the enlarged and constantly increasing uses of electricity, the number of persons indirectly, collaterally or remotely concerned with electric appliances is so large as to include a very considerable portion of the whole working population, and if the Legislature has in view the establishment of a license board for trolleymen, telephone girls, telegraph operators, lamplighters, cooks and janitors, the force of commissioners would soon become formidable. Yet, under the provisions of the bill, it has been contended that telephone operators and purveyors of push buttons would have to take out licenses at a cost of $25 per year. Such a bill is ridiculous, but measures equally absurd have found their way into the laws of New York and other states.

National Electric Light Association.

Preliminary arrangements are being made for the annual convention of the National Electric Light association at Chicago. On Monday last President Insull issued a call for a meeting of representatives of the electrical interests of the city at his office on Thursday afternoon at four o'clock "for the purpose of discussing what measures should be taken by local electrical interests for the entertainment of the visitors to the annual convention of the National Electric Light association, which will be held in Chicago on June 7th, 8th and 9th next." The following-named gentlemen were invited to attend the meeting:

W. W. Low, Electric Appliance company.
B. E. Sunny, General Electric company.
G. A. McKinlock, Central Electric company.
W. H. McKinlock, Metropolitan Electric company.
W. A. Kreidler, Western Electrician.
C. H. Wilmerding, Crocker-Wheeler Electric company.
F. W. Kohler, Kohler Brothers.
M. J. Insull, C. & C. Motor company.
R. J. Randolph, Excelsior Electric company.
Charles A. Munson, Fort Wayne Electric corporation.
C. D. Crandall, Western Electric company.
F. B. Badt, Meysenberg & Badt.
Charles E. Yerkes, Siemens & Halske company.
M. Coster, Westinghouse Electric and Manufacturing company.
J. R. Wiley, Standard Underground Cable company.
F. E. Donohoe, American Electrical Works.
J. B. Wallace, Wallace Electric company.
N. R. McLeod, Washburn & Moen.
L. A. Ferguson, Chicago Edison company.
John B. O'Hara, Western Electrician.
J. Holt Gates, Walker company.

Electricity in Mining Operations.[1]

By F. A. C. Perrine.

It is popular to say that we do not know the nature of electricity and therefore it is equally popular to use the name electricity as a conjuring word, assuming that its introduction into any particular system of operations would necessarily facilitate and cheapen them. Although it is true that we may now give a scientific definition for electricity as well as we can give a definition of light and heat, and a great deal better than we can define gravitation, we are not required to use an exact scientific definition in its engineering application. A sufficiently correct definition may be made by saying that electricity is a means of transmitting and utilizing energy without reference to the form in which the energy is to be employed. This definition includes the points of usefulness of electricity in engineering operations and excludes every other means of transmitting energy. Electricity has often been spoken of as a belt, but no belt can transmit and directly transform energy derived from the pulley of a steam engine into light, heat or motive power, as may be done by the use of this agency; and since it is thus readily transmitted to be used in all manner of energy transformations, it is capable of becoming the willing servant of the miner, as it has been successful in its application to other engineering operations.

In mining it has actually been successfully employed in milling, hoisting, haulage, pumping, drilling, lighting and in effecting electrolytic decomposition. Yet while these operations include almost the entire field of the miner, there is no doubt that the general introduction of this means of transmitting and utilizing power shows a decided tendency to lag behind other forms of development in mining operations along the Pacific Coast. For this there are undoubtedly two distinct reasons. In the first place, the machinery already developed has not been constructed with a view to the special conditions we find here, and in the second place the mining engineers and superintendents within this region have not obtained the special training that would enable them to adopt the machinery already constructed and adapt it to their special needs, or to develop new types of electrically operated machines to serve the particular problems we have here to face. In a sense, the lack of technical electrical training on the part of the mining engineers and superintendents who are operating our mines includes the first reason given for its tardy introduction in this field, since we should naturally expect the necessary machinery improvements to come from those most familiar with the particular conditions, and we may not therefore expect to see the best use made of this source of power transmission and development until those in charge of our mines have taken the pains to render themselves completely familiar with this branch of engineering. Even were suitable machinery available to-day these mining engineers and superintendents are not yet sure of themselves when left alone with the electrical machinery after the installing mechanic has returned to his factory, and until they are sure of their ability to do whatever repair work may from time to time be necessary, it will not be wise for them to attempt its use. A majority of the repairs must always be made on the ground and quickly, or the introduction of electrical machinery will have the effect of stopping all workings and flooding the mines while an expert is being sent from the nearest manufactory. Also such lack of training will generally bring about unnecessary break-downs from the development of little faults which the mechanic, untrained in this specialty, can never hope to foresee, since that which goes wrong in an electrical machine does not manifest itself to the eye or ear, or even to the hand, until it has reached disastrous proportions. The trained mechanic with his instruments can detect defects and repair them before they amount to break-downs. This training is something which the mining engineer must acquire, or his place will be taken by a new class of mining engineers, who can make use of this agency, for the many transmission plants now being developed in the mining regions will compel the introduction of electrical machinery as fast as the present contracts for water power shall expire and the cost of wood for steaming becomes excessive.

Again, as has been said, this new race of mining engineers will find before them many of the particular problems connected with the introduction of electricity into our mines entirely unsolved. The principal uses of electricity in mining operations at the present day are to be found in coal mines in the East, where the problems are altogether different from those met in gold and silver mining in either quartz or soft rock.

Perhaps the largest amount of power now used in these mines is absorbed in drilling, and while the electrical diamond drill is a successful machine, this drill cannot take the place of the pneumatic percussion drill, nor in this class of work can we make use of the coal auger or the under-cutting chain machine, so effective in coal mining operations. The electric percussion drill is to-day a failure in underground workings. Much surface quarrying has been satisfactorily done by its aid, but its great weight and the high temperature it attains place it at a serious disadvantage when compared with the pneumatic drill. Many times this problem has been attacked with great energy, and much money fruitlessly spent in an attempt to develop a satisfactory electrical percussion drill, with the sole result of proving that an electrical machine cannot be directly applied to this service. Whether there is or is not an indirect method of making use of electricity in drilling operations remains for inventive genius to show us.

But even in simpler needs than this of the percussion drill, it is evident that much engineering genius must be brought to bear on the problems before we can hope to see this form of energy successfully utilized. The best and cheapest wire cable to be used under the conditions here found is yet to be developed, and yet there is no need for any particular display of inventive ability. There is a necessity only for an engineering study of the particular conditions which are not at all those familiar to the manufacturers who are engaged in cable-making. They are prepared to furnish cables for the underground transmission of electrical energy, heavily insulated with rubber or other compound and protected by lead piping, but these heavy cables are difficult to maintain down vertical shafts, the lead being attacked by acidulated water and by the organic acids formed in the mine timbering. The manufacturers do not and cannot realize the immense importance of special construction for this field, although the information they now have at hand would enable them to construct a satisfactory cable for the engineer who is thoroughly familiar with the conditions under which the cable is to operate, and who has at the same time some knowledge of the materials available for their manufacture.

In the matter of pumping there is not a great difference between coal mining operations and those in gold, silver and copper mines, and in consequence there are to-day electrical pumps that can be used satisfactorily either for sinking or as station pumps, more satisfactorily and more economically than is possible by any system involving the transmission of steam. These pumps are not more economical than those operated by compressed air, where reheaters are employed, but as is well known the reheater is not always unobjectionable, and the electric pump has many advantages, even when compared with the use of the compressed air motor in similar service.

Electricity for haulage is also well developed, but as the haulage in the mines we are considering is of no very great importance, the advantage of the application of electricity does not carry much weight.

In spite of the fact that we know the electric elevator to be a safe piece of machinery when used under the conditions met within an office building or manufactory, the application of the electric motor to hoisting when the power is derived at long distance from one of the established transmission plants, is not entirely successful. These transmission plants deliver current at a high potential over a multiphase line, and although the induction motor is a good machine for steady power it cannot yet be considered thoroughly satisfactory when it is called on to start and stop frequently and to run at variable speed. This problem also demands considerable study on the part of the mining engineer, although it is a problem which the engineer may solve without attempting to become an inventor, since it is possible to transform the multiphase alternating current to a direct current by means of a rotary converter. This machine has been used satisfactorily in hoisting plants by applying to the hoisting gear a direct-current motor, which may be controlled by means of a rheostat, or even operated in two parts and controlled by means of the series-parallel controller. At the same time not every series-parallel controller is available for this use, since a difficulty is met, as the connection is changed from series to parallel and conversely. At that moment the motors must either be short-circuited or thrown on open circuit, and although this presents no difficulty in surface traction, where the cars maintain their speed on account of their momentum, opening the circuit of the motor while hoisting or lowering a car might cause an accident if the car was moving at a low speed without sufficient momentum for it to continue its travel during the time the change was being made in the connections. We thus see that the problem is one requiring a knowledge of the machinery to be employed as well as of the conditions under which it is to operate, which knowledge is only to be possessed by an engineer familiar both with practical mining and with electrical machinery.

Perhaps the most important application of electricity to mining at the present day consists of its use in electrolytic operations, and yet for these purposes we have as yet solved only the simplest problems, involving the deposition of a single metal, such as copper, from soluble anodes, and the recovery of other metals, such as gold and silver, from the slime remaining at the bottom of the electrolytic tanks. On the Pacific Coast this method of operation is far less important than the recovery of metal from leached liquors, could this latter operation be satisfactorily developed. Up to the present time it has not been attacked by anyone thoroughly familiar with all the conditions of the problem, whereas its solution would yield a rich harvest in the recovery of pure copper, in place of thousands of tons of copper now reduced by the cementation process.

This hasty review of the present condition of the field and of the improvements to be hoped for emphasizes a great need for training along the lines of the application of electricity to the particular problems of mining under the conditions as we find them. The solution of these problems is not merely something to be hoped for and something which may casually come in the future, but they are problems whose solution the present state of mining definitely demands, in view of the future expiration of water leases and the intense competition in mining, which will demand the employment of electricity furnished by the long-distance power transmission soon to be thickly scattered over the entire state.

[1] From the Engineering Journal.

Suburban Electric Service.

[From The Economist.]

It has been decided to equip the Evanston line [Chicago, Milwaukee and St. Paul Railroad company] for electrical operation. This will constitute a test of electrical operation as applied to steam-road passenger business, which will be fully as important as that of the New York, New Haven and Hartford road, undertaken about a year ago. The New York, New Haven and Hartford operates 12.3 miles by the third-rail system. As is well known, the eastern experiment has been successful form the standpoint of efficient service and lower operating expense as compared with steam. President Miller of the St. Paul said it could not be finally announced at this time whether the third rail system would be used on the Evanston line, but the presumption is that it will be, since the trolley has not been found very satisfactory for moving trains of the weight of steam road cars. The work of equipping the line for electricity will begin as soon as the City Council grants the necessary permit. For some time negotiations have been pending between the St. Paul road and the North Chicago Electric looking to the sale of current to the St. Paul, with which to operate the Evanston branch. As yet, however, the street railroad has not named a price which the St. Paul felt inclined to accept, and unless an understanding is reached in the near future the St. Paul will build its own power house. Mr. Miller says that the St. Paul will operate the road from Evanston to Chicago independently, just as it does at present. This step on the part of the St. Paul is obviously one of much importance, since if the test proves satisfactory other steam-road suburban lines will no doubt be equipped for electrical operation.

An English contemporary states that the Spanish government is still considering the advisability of constructing a direct cable to Cuba. At the same time it is negotiating with a French company which has a capital of $20,000,000. This company has offered to lay a cable from Hayti to Cuba within three months of signing an agreement, at an expenditure of about $1,000,000. The company does not ask for any money subsidy, but demands the right to work the cable for 25 years. The charge is to be fixed at one peseta (about 20 cents) per word, providing that the government will guarantee the company an average of 1,000 words per diem. The company undertakes not to make any claims for compensation or otherwise in the case of direct cables being established within the limits of this proposed time.

DEVELOPMENT OF THE TELEPHONE FIELD.

Praise for the Western Electrician's Independent Telephone Number.

The universal approval with which the "Independent Telephone Number" of the Western Electrician was greeted throughout the country and the substantial support that has since been accorded this journal's weekly telephone department are gratifying to all who are engaged in this work. The special telephone issue of February 26th is conceded to have been the most complete and interesting publication of the kind ever attempted. That it was appreciated is conclusively proven by the numerous letters of commendation that have since been received from all parts of the country and all classes of telephone workers. These letters show that a lively interest is manifested everywhere in the success of the movement, and that the aid and support of the Western Electrician is appreciated by those engaged in the development of this important industry. The following expressions are selected from the letters on file in this office:

Cabinet Manufacturing Company, Steubenville, O.: We think very highly of your Independent Telephone Number, and wish you much success.

William Roche, New York: The results from my "ad." in the Independent Telephone Number of the Western Electrician have been extremely gratifying.

Electric Appliance Company, Chicago: We think your Telephone Number is a very satisfactory paper and one that should do you a great deal of good in the telephone field.

Central Telephone and Electric Company, St. Louis, Mo.: We sincerely congratulate you on your Independent Telephone Number, as it is without doubt the best effort ever made in this line by any electrical journal.

Central Manufacturing Company, Chattanooga, Tenn.: We think your Independent Telephone Number is very creditable one and we think it should meet with the approval of all advertisers, as we feel sure they will get good results from it.

Keystone Telephone Company, Pittsburg, Pa.: Your Independent Telephone Number presents some very interesting reading matter to people interested in this line of trade, and we wish to congratulate you on the completeness of this edition.

American Electric Fuse Company, Chicago: We are more than pleased to inform you that your Independent Number of the Western Electrician of February 26th is more than we expected, and that it has done justice to all. We have received many inquiries from our "ad." in the above number. We believe the Western Electrician is the most valuable electrical periodical in existence to-day.

Farr Telephone and Construction Supply Company, Chicago: We are in receipt of the Western Electrician dated February 26th, which is called the Independent Telephone Number. We are very much pleased with this issue. The independent telephone companies should be proud of a journal that would devote so much space to their cause as this journal has. We think it is a great credit to the Western Electrician and hope that it will be appreciated by the independent companies.

Standard Telephone and Electric Company, Madison, Wis.: Your Independent Telephone Issue does you great credit, and is most complete as a beginning of the work which you have undertaken. That more of a similar character and of greater value to the independent telephone exchange proprietor will follow, we have no doubt. The first issue has very prominently called attention to manufacturing interests, but what follows should be for the good of exchange owners throughout the country generally.

Sterling Electric Company, Chicago: We wish to congratulate you upon your splendid effort by way of the publication of an Independent Telephone Number under date of February 26th. The editorial, typographical, mechanical and lithographical features are all gems of their own class. This number is a paper that, we feel sure, will be much appreciated and preserved for future reference. You are indeed entitled to a vote of thanks from the manufacturers and dealers in electric goods for the fair treatment which each has received at your hands in this publication.

Indiana Rubber and Insulated Wire Company, Jonesboro, Ind.: We have the Independent Telephone Number of the Western Electrician issued February 26th before us, and must say that we consider it a model number and one worthy of special notice. It will prove an excellent reference book for the purchaser of telephone supplies. We have received a great many inquiries the last few days, and nearly all show that they have seen our "ad." in the Western Electrician. All these inquiries are from nearly every section of the United States we would judge that you have covered the field well.

Independent Telephone Movement in Indianapolis.

Managers of independent telephone exchanges in Indiana and others interested in similar properties met at Indianapolis on March 3d to consider the outlook at Indianapolis for an independent exchange. The visitors were anxious that the New Telephone company of Indianapolis should get a franchise so that they might have connection through their toll lines with the capital. Among the visitors in attendance were the following named: Edgar W. Andress of Lafayette, C. S. King and William S. Stitt of Wabash, A. E. Reynolds, W. E. Nicholson, Ramsey and L. A. Frazee of Crawfordsville, E. C. Bickle of Elkhart, A. B. Irvin and J. L. Stone of Rushville, Will H. Craig, Charles M. Zion, E. Shirts and F. E. Heylmann of Noblesville, C. H. Reeves of Plymouth, John McGregor of Madison, George W. Beers, Charles McCulloch and Charles S. Bash of Fort Wayne. S. P. Sheerin, Harry Gates and Lewis C. Walker of the Indianapolis company were also present. The visitors presented long petitions from the business men of their respective towns, asking that the franchise be granted to the New company, as that would allow the independent companies connection with Indianapolis.

In the afternoon a hearing was given the petitioners by the Board of Public Works. The mayor, city attorney and city engineer were present, and the opposition company's stockholders had many influential business men on hand to urge its claims.

E. H. Andress, president of the Indiana Mutual Telephone company, explained the immense benefit to the state at large the granting of a franchise to the New company would be. He illustrated his remarks with a large map of Indiana, showing the independent companies' connections all over the state. The two companies have direct connection with the capital of the state. They served four times the number of subscribers that the old company does. This service would be doubled in another year.

S. P. Sheerin of the New company said: "There are now 137 towns in Indiana having independent exchanges. Many of these have no other telephone facilities whatever. There are connecting these towns, with the other, in various ways, 4,600 miles of independent toll lines. I mean by this, not 4,600 miles of wire, but 4,600 miles of roadway, between county seats and other good county towns, covered by the independent companies' lines, and upon these 4,600 miles of toll lines there are situated and supplied with telephones 1,500 towns, large and small."

George W. Beers, president of the Fort Wayne Home company, said the company he represented has connections with exchanges in seven counties in the state, and with exchanges in about the same number of counties in northwestern Ohio, reaching in all 6,440 subscribers. He had no means, he said, of knowing the exact number of subscribers reached by the Bell company from Fort Wayne in the same territory, but it seemed to him safely within the facts to estimate the number accessible to the Fort Wayne exchange at 3,211. He argued that the city of Indianapolis should open the way for connections with independent lines, since their patrons outnumber the old-line users. The board took the subject under advisement.

Home Telephone Company Claims Victory.

W. H. Bryant, manager of the Home Telephone company of Mobile, Ala., claims that the decision of Judge Toulmin in the case of the Western Electric company on the Scribner multiple switchboard patent, is a practical victory for the Home company. He said:

"The Home Telephone company is the only one that ever put up a fight against the Western Electric company, who have been claiming everything in connection with a multiple telephone switchboard. They at first claimed their seven specifications of the patent to be infringed, but abandoned all all but three at the hearing of the case. The decision of Judge Toulmin sustains two of the three specifications. It is practically a victory for us, massmaterial to our system and can be obviated by the company at a small expense, and will not in any way effect our service, as we use an entirely different system from any other telephone exchange. The rest of the making change in our present board become within the points sustained are merely nominal and can be made without interfering with our service for a moment, and in view of that fact we will proceed to do so to avoid any injunction based on this decision. We have 60 days in which to make the change before any injunction becomes operative under the decision, and we expect to be able to make the change within that time, should we decide to make it at all. As to an appeal from Judge Toulmin's decision, we have not as yet decided as to our course, but in view of the fact, as I stated before, that the change will not affect our service and is not excessive, I myself would be inclined to make it and let the decision stand as it is, without appeal."

Bell Company's Plans Miscarry.

[From the Chicago Record.]

The decision of Judge Toulmin of the United States Circuit Court for the Southern District of Alabama in the case of the Western Electric company of Chicago against the Home Telephone company of Mobile and Albert S. Lyons and Adam Glass, its president and treasurer, has a peculiar significance aside from the determination of the validity of the claims of the patent involved. The action was a suit in equity on a patent granted Charles E. Scribner of Chicago for a multiple switchboard, and was consequently of great interest to telephone companies operating large exchanges and using apparatus not made by the Bell licensees. Scribner is the chief expert of the Western Electric company, which is really the manufacturing branch of the Bell interests, as the American Bell Telephone company owns a majority of the stock of the Western Electric company and directs its policy and management. Consequently, it may be taken for granted that any litigation instituted by the Western Electric company is dictated in the interest of the powerful corporation of which it is a part.

On its face the suit in question was merely an action to sustain a valuable patent and a petition for injunction against the alleged infringer, but behind it all was plainly an attempt to create a precedent for actions against individuals and firms in effort to cripple the anti-Bell companies that are growing so numerous and powerful throughout the country.

It looks very much as if the Bell company attempted to steal a march and that its plans miscarried. The avowed object of the litigation was only partially accomplished, the court sustaining two of the four claims for which the action was instituted, but prohibiting the enforcement of the injunction within 60 days after the rendering of the decree. This latter provision was of itself a great victory for the defendant, as it was made with the avowed purpose of preventing the complainant from taking advantage of the defendant and summarily closing its exchange. The court declared that this time be allowed "on account of the public inconvenience that might result in summarily enjoining the defendant in the use of its switchboard." Similar provision made in the decree as entered in the record, thus establishing a valuable precedent in this particular class of causes.

But by far the most important feature of the decision and opinion was that directing that the complaint against the individual defendants, as defendants, the president and treasurer of the defendant company, be dismissed. The court finds:

"It is not shown in the evidence that defendants Alfred S. Lyons and Adam Glass have in their individual capacity violated any of the complainant's rights, or that they have individually derived any profit or advantage from the patent sued on. No reason is shown why a decree should be rendered against them as individuals. As to them, therefore, the bill is dismissed at the complainant's cost."

The importance of this ruling arises from its effect upon the policy of the Bell company in its litigation against the independent interests. The parent company's plans were based upon the assumption that it could pursue all who lent aid and encouragement to its rivals, and it hoped by instituting suits against individual users of "independent" instruments and stockholders in anti-Bell exchange companies to spread consternation in the ranks of rival concerns and their supporters. It would seem, however, as if Judge Toulmin's decision had raised up a barrier that could not be surmounted and that the campaign of intimidation was to be safely waged.

At present the situation has more of promise for those who are opposing the attempts of the Bell interests to restore a monopoly.

Telephone Lines in Lee County, Ill.

The establishment of a complete telephone system by the independent interests in Lee County, Ill., has progressed so rapidly that the management now announces that it has succeeded in every case beyond its anticipations. The company commenced building a year ago last October and at that time did not have a subscriber. The first line was from Amboy to Lee Center, five miles, and Amboy also secured an exchange. A line to Eldena and Dixon was built and one telephone placed in the court house at the latter place, which was all that was placed there until the latter part of May. Then from Amboy a line was built east to Shaw, West Brooklyn, Compton and Pawpaw and south from Shaw to Sublette, and from Dixon to Grand Detour. This work was completed about January 1st and the company commenced getting subscribers to compete with the Central Union company, which had been established in the territory 15 years. The company concluded to charge $1.50 per month for residence service, $2 for offices and $2.50 for commercial business use. About the same time the Central Union company commenced putting in the multiple system, which it claimed was an improvement, and cutting prices to $2 per month. It then had about 160 subscribers, but the change did not prove satisfactory, and now the Central Union is changing back to the old style of operation and cutting prices again. At

present its rates are as low as $15 and $20 per year, but as the independent company has 250 subscribers, including all the old company's excepting about 30, and is giving subscribers free use of all lines in Lee County and Whiteside, besides Rochelle and Mendota, it thinks that free service, even, on the part of the Bell interests would do no harm. The Lee County Telephone company now has exchanges in Lee County at Dixon, Eldena, Ambcy, Harmon Sublette, West Brooklyn, Compton, Pawpaw, Steward, Ashton and Franklin Grove; and toll offices at Grand Detour, Nachusa, Chicago Road, Flagg, Lee Center, Shaw and Walton. It connects with the Whiteside County company at Prairieville, with the Ogle County company at Rochelle, and intends to connect with the DeKalb County company this spring at Lee Station on the county line and give subscribers the free use of all connections in the adjoining counties, but where a message crosses an adjoining county into a county beyond, then a toll of 10 cents will be claimed by the county crossed for service. The Lee County Telephone company has used the Western Telephone Construction company's switchboards and telephones mostly, and employed the common return system. It has 7,000 feet of cable in use in Dixon and the entire system is working satisfactorily.

Independent Telephone Exchange Company in Buffalo.

[From the Niagara Falls correspondent of the Western Electrician.]

To all appearances the Bell people are to have very active competition in Western New York, for in addition to the strong company which, as I reported recently, has been incorporated to to business in this field, another company of equal strength has filed incorporation papers in Albany to do a telephone business in the same field. This latest company is named the Buffalo Telephone company, and the capitalization is $500,000. At a meeting of the stockholders the following-named gentlemen were chosen as directors of the new company, and their names appear as such in the certificate of incorporation: George Birge, Daniel N. Lockwood, Leonard B. Crocker, Charles E. Williams, James Kennedy, William H. Kinch, William B. Hoyt and Reuben J. Getz. Humphrey, Lockwood, Hoyt, Greene & Yeomans are the attorneys of the company. The members of the company say they are out for business and are ready to commence construction as soon as they can get a charter from the city of Buffalo. Each company strenuously denies that it was formed to block the game of the other. In its certificate the company states that it proposes to operate a telephone line in Buffalo, to Lockport, Medina, Albion, Brockport, Rochester, Depew, Lancaster, Akron, Batavia, Churchville, Tonawanda La Salle, Niagara Falls, Lewiston, Youngstown, Hamburg, Angola, Silver Creek, Dunkirk, Erie, Pa., Ashtabula and Cleveland, O., and also in cities and villages other than those mentioned, in Erie, Niagara, Orleans, Genesee, Livingston, Wyoming, Monroe, Chautauqua and Cattaraugus counties. The people of Western New York welcome competition with the Bell company, and there is no doubt that the new companies will find it easy to get franchises in all the cities and villages if they show their sincerity in fighting the Bell people. However, the hope of the people is that the interests of the two companies will not be allowed to conflict so as to render their efforts ineffective in freeing the territory in which they propose to operate from the Bell monopoly. It is already intimated from Buffalo that the Buffalo Telephone company will have no trouble in securing a franchise in that city, its application having been presented before that of the Western New York Telephone company. The first mentioned company is said to have perfected arrangements for a circuit with systems in other cities not controlled by the Bell Telephone company. The organization of these two new companies no doubt means a bitter fight with the Bell people, but public sentiment in Western New York will be with the new companies every time.

Telephony in London.

There are troubles in connection with the operation of telephone exchanges in England as in this country, as the following comment from a London financial journal illustrates:

"The telephone company's service is becoming absolutely unendurable. Last night at five minutes to 11 an attempt was made to communicate with our offices and no connection could be obtained. Repeated rings till 11.15 were unavailing, and when a call through another exchange compelled an answer the young lady in charge at 'Gerrard' explained that she had been too busy to attend in the meantime. The correspondent who was endeavoring to communicate informs us that he does not send the usual present of gloves or game to the clerk in charge of the Gerrard exchange, and this doubtless explains the young lady's preoccupation. Complaints to the telephone officials are absolutely useless; the question, therefore, resolves into sending presents to the subordinate officials or remaining unserved. How long London will put up with the nuisance it is impossible to say, but the sooner a league is formed to remedy the abominable evil at present existing the better it will be for all concerned."

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Richland County Telephone company has absorbed the Richwood-Eagle company in Richland County, Wis.

The requisite number of subscribers has been secured in Muscatine, Ia., and the Mississippi Valley Telephone company will put in an exchange.

A telephone line will be constructed between Highland, Wis., and Clyde.

The council of Eau Claire, Wis., has taken a hand in the telephone war at that place by passing a resolution prohibiting the Wisconsin Telephone company from erecting additional poles or lines in the streets without a permit from the mayor and council. Charges have been made that the old company is interfering in every way, which are denied by its officers.

The new telephone company at Centerville, Ia., is securing many subscribers. Connection is to be made with nearly every place in the county.

The Iowa Telephone company has put in a new switchboard at Dubuque, Ia., to accommodate increasing business.

The Iowa Telephone company's application for permission to place additional poles for a long-distance connection at Waukon, Ia., was denied, the council fearing it meant trouble for the Standard Telephone company.

The Nicollet County Telephone company will build lines between St. Peter and Winthrop, Minn. Arrangements are being completed to form a company.

The Iowa Telephone company has completed long-distance telephone connection with Waverly, Iowa.

The application of the Minnesota Central Telephone company for long-distance franchise into St. Paul is being considered by the council. This company has just been granted a franchise in Minneapolis. Charges have been made by some of the assemblymen that the manager of the old company had approached them and asked them to absent themselves from the meeting and break a quorum. This, Mr. Freedy indignantly denies. He suggests that a complete examination be made of the company's lines and system, but denies that he has in any way attempted to do any underhanded work. The Mississippi Valley Telephone company is also an applicant for a franchise for a local exchange. It also has just been granted a franchise in Minneapolis.

A stock company is being arranged to build a telephone line between Billings and Lewiston, Mont.

The Eureka Telephone company has been formed at Eureka, S. D., and will put in an exchange. It will connect with the Dakota Central Telephone company's long-distance system.

Efforts are being made to secure an exchange at Elkton, S. D.

The Wisconsin Valley Telephone company's long-distance wires have reached Washburn, Wis.

The Northwestern Telephone Exchange company will extend a line from Lake Crystal, Minn., to Winnebago City, this season. Also from Blue Earth City to Elmore, and from Fairmont to Heron Lake. A new line will be put in from Mankato to New Ulm and probably as far west as Tracy, Minn.

The Mankato Citizens' Telephone company has secured 200 subscribers, and practically no soliciting has yet been done.

The La Crosse and Southeastern Telephone company held its annual meeting in La Crosse, Wis., and decided to extend lines to Cashton, West Salem, Bangor, Sparta and other points.

The Litchfield Telephone Exchange company, recently organized, proposes to extend lines to Eden Valley and other points in the county.

It is understood the American Telephone and Telegraph company will gain admittance to La Crosse, Wis., by the Wisconsin Telephone company building a line to West Salem, the nearest point reached by the American. The council of La Crosse has demanded as the price of admission to the field that the company give connection with all telephone companies in the city, and this the company very decidedly refused to do. The La Crosse Telephone company, an independent company, will seek to bring the lines of the Wisconsin Valley Telephone company to that city to meet the competition.

The Midland Telephone company of Ellendale, N. D., is to be extended to Monango, Oakes, Edgeley, Kulm and La Moure, making a complete circuit of La Moure County. It will later connect with Fargo and towns on the east.

An effort is being made to establish a telephone exchange in Allerton, Ia. The matter will be submitted to vote March 28th.

Western Telephone Manufacturing Company.

Among the enterprises incorporated at Springfield, Ill., last week was the "Western Telephone Manufacturing company at Chicago; capital stock, $2,000; incorporators, M. B. Kennedy, W. A. Bisland, S. C. Platt."

The name of this concern is similar to the one with which the incorporators are now identified, the Western Telephone Construction company. Mr. Bisland, in behalf of his associates, declined for the present to divulge the plans of the new corporation.

The Telephone Situation.

By J. J. Nate.

Part I.

"History repeats itself." In no enterprise of recent years has the truth of this saying been more fully realized than it is to-day in the work and organization of the independent telephone companies throughout the United States. In view of the fact that the telephone in its fully developed state has now been in general use for many years, and that the public at large is more or less familiar with its workings, it seems strange to a casual observer that this condition of affairs should exist. To those engaged in the work of manufacturing apparatus, and whose business brings them in close touch with promoters and organizers of independent telephone work, it is not at all strange, nor need it necessarily be so considered by anyone who appreciates the fact, that the general public has known very little of the scientific or financial work of the Bell company during its many years of monopolistic control. In a general way it does know that the Bell company's rates and methods of operation resulted yearly in large dividends, and that poor men became rich and rich men became millionaires in a very few years.

To the thinking and enterprising citizens of our country who have analyzed these conditions, two facts have been prominently established: First, that a telephone company could be successfully operated and pay a handsome interest on the investment where rates were much lower than those heretofore charged by the Bell company or its licensees; second, that the Bell company cannot necessarily retain its prestige on the ground of "a natural monopoly," if legitimately and thoroughly dealt with in fair competition. These are the men who have taken hold of this matter, and the result to-day is most flattering and satisfactory to promoters, and no doubt quite as discouraging to the Bell company and its licensees.

Time must determine whether it will be possible for the Bell company to duplicate the methods which for so many years retained to the Western Union Telegraph company its entire control of the telegraph business of the United States. Two factors enter somewhat into this possibility—one, an eventual and complete purchase of opposition interests; the other, a final adjudication sustaining the Bell company claims for the Berliner patent, on merit. The matter will first be dealt with by the United States Circuit Court of Appeals, and if in the several districts comprising the court there is a consensus of opinion there would probably be no possibility of carrying such suit or suits to the higher court, is true, but it is very generally believed that in no final court will the Berliner claims be sustained. Should there however exist a difference of opinion, it may result in taking the suit in question to the Supreme Court of the United States.

It is not, however, the intention in this paper to discuss the Berliner patent, because the questions naturally presented have been answered by men of legal ability, experience and learning many times and in many ways during the last two years. With a hope that some prominent evils may be eradicated and that something may be learned of the true situation of telephone work, its various phases are presented as fully and as accurately as time and facts thus far established will allow.

Organization.

Popular methods employed by promoters in the work of independent exchange organization, if legitimate, are, in nearly every instance, successful. These methods incorporate a canvass for subscribers at rates varying from $1.50 to $5 per month for telephones, according to population; a franchise for the construction and operation of an exchange covering a period of not less than 15 years; the employment of one or more practical and experienced telephone men, a wise selection of operators and the installation of an exchange under the supervision of someone who understands the work of telephone construction thoroughly.

The cost varies somewhat and is dependent on many conditions. It has been proven beyond question that a 100-number exchange can be constructed at a total outlay of $4,000, using the best of apparatus and pole-line material, No. 14 galvanized iron wire with a No. 10 hard-drawn copper return wire, poles ranging from 30 to 50 feet in height, having four to seven inch tops, office, pole and line-distributing facilities, switchboard and telephones of unquestioned merit. Such an exchange, operated at a cost to subscribers of $1.50 per month for resident and $2.50 for business connections, will net not one cent less than 20 per cent. on the original investment, if properly conducted. An exchange of precisely similar construction for 800 subscribers can be installed for $50,000, and will, under similar conditions, net anywhere from 10 per cent. to 20 per cent., according to apparatus used and economy exercised in operation. It would seem from such information as we have at hand that an exchange of from two to four thousand subscribers can be installed as a full metallic circuit, with an underground distribution of practically one mile from the office and of "A 1" construction at from $100 to $125 per connection, and if operated at rates ranging from $ 6 to $60 per year, the interest on

the investment should in no case be below 12 per cent., and it has been stated will net not less than 18 per cent at the lower rate indicated.

These statements are not made at random, nor without a knowledge of what they imply. On the contrary, there are now independent exchanges in operation installed three years ago that have, after deducting operating and maintenance expenses from the gross earnings, paid back to promoters dollar for dollar of their original investment, practically 33 per cent. on the original capital. From reports received over the signature of reputable business men engaged in independent-exchange work in different parts of this country, it is ascertained that the interest on their investment varies from 15 to 35 per cent. at rates varying from $1.50 to $4 per month for telephone service. Companies which were unfortunate enough in the beginning to employ incompetent men as superintendents in charge, and which purchased cheap or unsuitable apparatus, long since abandoned or remodeled, have found it necessary to devote their entire earnings to the work of operation and maintenance, and even in this class are to be found exchanges which last year paid eight per cent., after a reorganization and reconstruction of their plant. It is true a number of enterprises have fallen through and about 70 exchanges have either failed, reorganized, sold out to to the Bell company or still remain in the fight. Another proof as regards the earning capacity and cost of maintaining a telephone-exchange plant, and one which, to the writer, is more convincing than the information obtained from the independent companies, lies in the experience covering a period of over 19 years while employed in an operative and executive capacity by the most prominent Bell company exchange west of the Alleghanies. The entire apportionment of working accounts devolved upon a department over which the writer had full charge, and an inter-checking system was adopted between the various departments, resulting in a full and complete statement showing total cost of maintenance and operation monthly. From the knowledge thus acquired, the writer well knows that in a very large city a rate of $80 per year will net a handsome interest on the actual outlay necessary for the complete installation of a very big exchange. Don't let us forget, in the consideration of that rate, however, that royalties and $5,000 to $20,000 salaries are not included. It is also a matter of record that in the city of Chicago, and presumably in other large cities, the rate was $75 until after the Western Union deal was consummated, soon after which an advance to $125 per annum was made. The operating and maintenance expense of those days would compare favorably with the same item in the work of the independents at the present time, with a fair difference in favor of the new companies, owing to experience and improved class of material and apparatus, and also because labor is obtainable at more favorable rates per diem.

It is true of the Bell company that after nearly 10 years came the installation of multiple switchboards and construction of underground plants, in which millions were invested in Chicago and other large cities, which, for a time at least, must have taken all and possibly more than the total receipts of the companies interested.

Equipment.

An exchange of from one to three hundred subscribers can be handled by one or two operators at an average speed of 10 seconds on all connections furnished, and the apparatus need not necessarily be of an elaborate character in order to keep up this average without hardship to the operators.

In making a selection of exchange apparatus, purchasers should consider a few vital points, otherwise maintenance expenses will grow and subscribers become dissatisfied.

A switchboard for a small exchange should be of such reliable and simple construction that little if any attention is required, except in the nature of daily line tests and occasional repairs to cords or other auxiliary apparatus which may be subjected to severe and constant use. The instruments used in such an exchange should be of substantial and reliable construction. An automatic generator with switch of good mechanical construction, supplied with non-corrosive and positive contact points, a transmitter which will not pack and requires no adjustment, batteries of sufficient recuperative quality and merit to give an average service of eight months, a permanently adjusted receiver of the Bell type and well made, together with lightning arresters and proper terminal facilities, constitute all that any moderate size exchange requires in the way of apparatus.

In larger exchanges one or more men at good salaries must be employed who understand thoroughly the telephone business, both practically and theoretically. Switching facilities for distribution of connections throughout such an exchange must be provided for, and they should be of a character to admit of quick service and so arranged that subscribers are at all times in communication with the exchange, and I may here say that multiple boards are not at all essential to such a result.

[illegible] Operation.

Some supervision by the owners is required but not necessarily close attention, if care is used in the selection of a man to take charge. In a small exchange such a man can be secured for $50 a month—one who has had enough experience in the business to repair lines, keep the board and instruments in working order, make all the collections, and, if need be, keep the books. Fortunately, there are many such to be found. As a rule they are men who have served the Bell company faithfully and to little purpose. In case of severe interruption to the service, assistance can be secured at no great expense. For the office work one or two bright operators and a night boy will handle an exchange of 200 to 300 numbers very nicely, at a total expense per year about as follows:

Expenses

Rent	$ 120
Light and fuel	75
Manager	600
Two operators	420
Night boy	120
Battery maintenance	100
Line and sundries	100
Total	$1,535

Receipts.

One hundred telephones at $1.50 per month	$1,800
One hundred telephones at $2.50 per month	3,000
	$4,800
Less	1,535
	$3,265

Cost of plant, 200 telephones at $50, $10,000.

This result shows an interest on investment of over 30 per cent., from which it can readily be seen that 10 per cent., or $1,000 per year, can be allowed for operation and maintenance, or as a reduction in the earnings, or for both, and the net result will still be at the rate of 20 per cent. The same can be claimed for a plant of 100 telephones, as one operator only is required, and the cost of maintenance lessened by one-half. The rate of earnings for larger exchanges, unless at higher rates for service, will run somewhat lower. There are many unforeseen expenditures incident to an exchange of 500 to 1,000 subscribers which do not as a rule enter into the expense account of smaller exchanges, such as burn-outs from crossed wires, line reconstruction as new subscribers are added or repairs to lines after severe storms, increased taxes, damage suits, rentals for right of way on private property, and last, a regular inspection of subscribers' apparatus. Still, with all these adverse conditions, I can point out exchanges of 700 subscribers, at rates of $1.50 to $2 per month, paying eight per cent. on the capital stock, which may mean a better interest to preferred stockholders. With so favorable a showing, is it to be wondered at that capital is daily going into the independent telephone business? True, the subscriber may well ask, "If you are doing well, why not reduce the cost of telephone service?" Right here applies one of the few good arguments employed by the Bell company as an excuse for high tariff rates: "A telephone exchange company is at all times carrying a risk which cannot be estimated, and for which some provision must be made" not at the exorbitant rates heretofore existing, but at rates which may be termed "a happy medium." If no one meets with an accident in consequence of carelessness on the part of employes, no total destruction of switchboard by fire or water and temporary loss of rentals, no damage suits for injury from lightning because of improper wiring and many other similar causes—then, and only then can the promoters realize the handsome returns looked for, to which might be added that experience must be paid for and that is precisely what many of the independent companies have been doing for the last three years. But through it all they are still progressing, and, having passed the experimental stage, are now on the road to success.

COMMUNICATION.

National Telephone Manufacturing Company.

To the Editor of the Western Electrician:

As you doubtless are aware, the National Telephone Manufacturing company has been engaged since August, 1895, in the defense of a suit brought by the American Bell Telephone company for infringement of the patent of the so-called "Berliner" invention, which it is claimed covers all forms of microphone transmitters or contact telephones, and which has been deemed by the United States Patent Office worthy of protection by letters patent. The suit is a dangerous one, for behind this patent looms up the great telephone monopoly with its prestige and financial power.

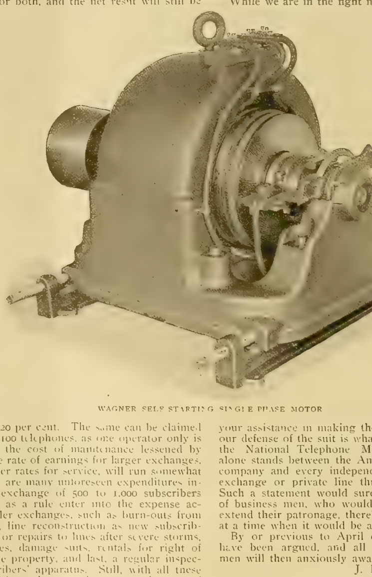
We have not only been handicapped by the heavy and enforced disbursements always attending such litigation, but we also have been compelled to carry an additional burden by and because of the circulation of iniquitous reports that the suit was a dishonest one and that we were in collusion with the Bell company in our defense.

Our answer is very simple, for the leading officials of the National Independent Telephone association, which was organized in Detroit last summer, have thoroughly investigated the situation and will corroborate the fact that our defense of the suit could not be improved upon.

While we are in the fight may we not count upon your assistance in making the facts clear to all that our defense of the suit is what it should be and that the National Telephone Manufacturing company alone stands between the American Bell Telephone company and every independent telephone factory, exchange or private line throughout the country? Such a statement would surely disabuse the minds of business men, who would no longer hesitate to extend their patronage, thereby tendering assistance at a time when it would be appreciated.

By or previous to April current our cause will have been argued, and all independent telephone men will then anxiously await the court's decree.

J. D. LEATHERBEE.



WAGNER SELF STARTING SINGLE PHASE MOTOR

Wagner Self-starting Single-phase Motor.

The Wagner Electric Manufacturing company of St. Louis announces the enlargement of its line of self-starting, single-phase, alternating-current power motors to include 10 and 15 horse power sizes for current of 60 cycles and $7\frac{1}{2}$ and 10 horse power sizes for current of 133 cycles. These motors are identical in principle with the smaller sizes, differing from them merely in point of mechanical construction. In the smaller sizes the operation of starting is performed by hand, while in the new sizes this operation is automatically performed. The commutators in the new sizes are of the radial form, the brushes running against the end in a manner quite clearly shown in the cut. In starting, the armature and field are connected in series. When the armature has run up to the requisite speed, this connection is automatically broken by a governor device within the armature body, the brushes being lifted off. Simultaneously the field alone is connected across the line and the armature completely short-circuited on itself. The motor then runs purely as an induction

motor. Only two wires from the line lead to the motor. No starting resistance box is required, no auxiliary device of any kind. A third binding-post provides an extra end to which the line wire may be connected when the supply voltage is low. The rated motor voltage is 104.

R. & H. Motor Starter.

The automatic starter and switch now offered to the electrical trade by Ross & Hailey of New York has a number of advantages which recommend it especially for elevator and printing-press installations, or for any similar class of work. This device is built of the best material, and of very heavy construction, so as to mechanically stand the strain brought upon it.

COMMUNICATIONS.

A Question of Identity.

To the Editor of the Western Electrician:

You will doubtless learn that the Warren Electric company of Chicago, Ill., is in the hands of a receiver.

To correct any misapprehension growing out of the similarity of firm name, we hasten to inform you that the appointment of a receiver for the Chicago company, an Illinois corporation, has no bearing whatever upon the Warren Electric Manufacturing company of Sandusky, Ohio, and does not affect it in the slightest degree.

WARREN ELECTRIC MANUFACTURING COMPANY. C. F. Mack, Treasurer.

Sandusky, O., March 3, 1898.

Another Question of Identity.

To the Editor of the Western Electrician:

It seems that some company which has a name similar to ours has been unfortunate enough to pass into the hand of a receiver. We of course sympathize with our namesake, but desire to inform the trade that while we have troubles this is not one of them and that we are still selling anti-trust lamps in large quantities.

WARREN ELECTRIC AND SPECIALTY COMPANY.

Warren, O., March 7, 1898.

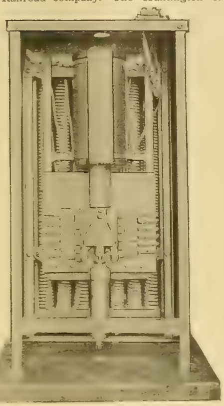
CORRESPONDENCE.

New York Notes.

New York, March 7.—Owing to the extent to which electrical apparatus is used in modern warships and coast defenses, the war excitement has an especial interest to electricians, apart from their patriotism as citizens. Many prominent electrical men were formerly naval officers, and at least one of them, Mr. Sprague, is said to have volunteered his services to the government. If war should come, the government will need the help of a larger number of trained electricians than it has in its service at present. Indeed it is stated that a number of men belonging to the Electrical Workers' Union of this city have been already engaged for service in the navy. Delegate Hoadley of the union asserts that six of its members were engaged on Friday by an officer of the Brooklyn Navy Yard and will be sent to the Mare Island Navy Yard in San Francisco. It was also said that Daniel Sullivan, another member of the union, was under engagement for service on the Holland submarine torpedo boat. Sullivan has served in the navy before. Other members of the union have been told to hold themselves in readiness for employment in the navy. Many machinists, steam fitters and boilermakers are also being engaged by naval officers.

The commissioner of bridges has made public the financial statement of the Brooklyn bridge for the month of February. It shows a falling off of $10,000 over February a year ago and of $18,000 over January of the present year. The falling off is unquestionably due to the trolley-car system now running on the bridge. The Brooklyn trolley companies started running cars regularly across the bridge on February 16th. Since then they have been running an average of 2,134 cars a day across the bridge, and they expect to increase this number to an average of 3,500. The loss to the bridge has not been a total gain for the trolley companies, for they charge no extra fare for the ride across the bridge. Before the new system the trolley companies charged the same fare for each passenger that they do now. They carried then a large percentage of the people they carry now. The increase in their traffic through crossing the bridge is at the expense of the elevated railroad.

Near-by electric railroads show increased activity. Application was made to Judge Gaynor in the Supreme Court in Brooklyn on Saturday for a writ commanding the trustees of the village of New Rochelle to give a hearing to the New York, West Chester and Connecticut Traction company, which desires to construct an electric railroad from Port Chester to the Harlem River. Consents, it was asserted, have been obtained to operate the road through Pelham, West Chester and Mamaroneck. The counsel for the road said that the West Chester Electric company, the New Rochelle Electric company and the Huguenot Electric company have had a hearing, and that the West Chester company had obtained leave to construct a road, but that the New York, West Chester and Connecticut company had been excluded from consideration. He said that his company intended to charge a fare of only five cents for the entire distance, whereas the other companies wanted to gridiron the district and charge 10 or 15 cents. Briefs were submitted and decision was reserved. At Mamaroneck, on Thursday, the village authorities granted to the Tarrytown, White Plains and Mamaroneck Railroad company a franchise to build an electric street railroad from Mamaroneck to White Plains. The road is to be in operation on or before July 1st, and will connect with a branch already in operation between White Plains and Tarrytown, forming a direct line from Long Island Sound to the Hudson River. Another recently granted franchise is that given by the trustees of New Rochelle to the Union Electric Railroad company to construct and operate trolley lines over the local streets. The company has filed a bond for $50,000. The franchise gives the right to operate electric cars from the New Haven railroad station to Starin's Glen Island dock, and thence to Larchmont Manor; also a line to Pelham, which will connect there with the present Mount Vernon line, giving the company a through route from Larchmont to One-hundred-and-twenty-ninth street, New York. On Long Island the Huntington railroad has been sold to the Long Island Railroad company. The Huntington railroad is three miles long and connects the village of Huntington with the Long Island railroad. It is the intention of the purchasers to change the motive power from horses to the overhead trolley system. M. S.



R. & H. MOTOR STARTER.

Canadian Intelligence.

Ottawa, March 7.—It is said that the St. Clair Tunnel company contemplates converting the motive power for the tunnel from steam to electricity. The matter is understood to be under consideration by Joseph Hobson of Montreal, chief engineer of the company.

At the next session of the Manitoba Legislature a local company will ask for a charter to build an electric railway from Winnipeg to St. Andrew's Rapids, and through the municipalities of Springfield, St. Boniface, Kildonan, St. Paul's and St. Andrew's. The company also proposes to construct sawmills, boats, telegraph and telephone lines.

There is a movement on foot to get an electric-railway service for the Island of Orleans, near Quebec. It is reported that a charter will be asked for an electric railway around the island. The power is to be obtained from Montmorency Falls.

It is understood that Engineers Keating of Toronto, Pearson of New York and Wanklyn of the Montreal street railway have visited the new Chambly works, Quebec, with a view to reporting upon the feasibility of using that power for the Montreal street railway, which, in producing its own power, expends about $360,000 per annum, while the Chambly people have, it is said, offered to furnish the company with power at a reduction of 25 per cent.

Work was begun last month on the power house of the Hamilton Cataract company, near Decew Falls, Ont., and it is being rapidly pushed toward completion. The building is to stand within a few feet of the edge of the stream and above high-water level, where the precipitous banks rise nearly 275 feet in height. When completed the power house will be 174 feet in length and 42 feet wide, and the walls 30 feet in height. It is to be constructed throughout of steel, faced with brick, and have cemented floors.

The progress which has been made in lighting by electricity is well illustrated by the statement contained in the report of the commissioner of inland revenue for Canada that there were 187 electric-light companies registered in the Dominion under the inspection act during the year.

From the plant which the West Kootenay Electric Light and Power company is erecting at Bonnington Falls, B. C., it is expected that the transmission of power to the Rossland mines will be commenced early this month. Bonnington Falls, where the power house is situated, lies about 11 miles below Nelson, B. C., on the Kootenay River. Water is conducted to the reservoir from the river by a canal 22 feet deep, cut out of rock for a distance of 640 feet. The two turbine wheels are attached directly to the generators. There are two generators, having together a capacity of 2,500 horse power. They operate at 180 revolutions per minute.

The Cornwall Electric Railway company has submitted to the Town Council of Peterboro, Ont., a scheme for the construction of an electric railway from that town to Chemong and Lakefield. The company proposes to lease the Chemong and Lakefield lines from the Grand Trunk railway, convert them into electric roads, and take over the freight business. The cost is roughly estimated at $350,000.

A new proposition for the supply of electric power to the city of Toronto has been made by the Georgian Bay Ship Canal and Power Aqueduct company. The price quoted is six mills per electric horse power per hour, the company agreeing to supply 2,000 horse power within two years from date of contract.

A live question now before the City Council of Ottawa is whether the Deschenes Electric Light company will be permitted to compete for electric lighting in this city in opposition to the Ottawa Electric company. A. V. W.

Northwestern Notations.

Minneapolis, March 8.—A stock company will be formed at Shell Lake, Wis., to install an electric-light plant.

The rates for electric lighting by the municipal plant at Valley City, N. D., have proved too low to meet all expenses. The income for four months has been about $310 per month and the expenses $390, the difference having to be charged to electric street lighting.

The council of New Paynesville, Minn., will be petitioned to submit the matter of electric lights to vote at the coming election.

The Minneapolis and Anoka Electric Suburban Railway company has been incorporated with $100,000 capital stock by Henry Lee, I. A. Caswell, A. E. Giddings, Thomas and John Coleman, John Dunn, Hiram Thornton, O. L. Cutter and Frank Hart. It is believed the Twin City Rapid Transit company is behind the company. The Twin City Rapid Transit company has just been granted permission to build a power dam across the Mississippi River at Coon Rapids, on the line of the proposed road.

P. Daugherty of St. Paul secured the contract to construct the electric-light and waterworks plant at Ortonville, Minn.

The Twin City Rapid Transit company will soon begin work changing the Fourth street cable line in St. Paul to an electric line. During the progress of the work tracks will be laid on Selby avenue from Dale street and Farrington street to the Rondo line. This will avoid transferring at the top and bottom of the Selby avenue hill, as was at first proposed, during the change.

Lake City, Ia., voted overwhelmingly for electric lights, and the contractors will soon begin work on the system.

The council committee appointed to investigate the feasibility of a municipal electric plant for St. Paul will shortly take bids on such a plant. The estimated cost of a plant with 1,500 arc lights capacity is $350,000.

Paul H. Sanborn, who has been granted a franchise at Waupaca, Wis., for an electric railway to the Chain o' Lakes, says that work will be begun on the proposed line at once.

The question of a municipal electric plant for Des Moines, Ia., will be voted on again at the coming election, the recent court decision having nullified the first vote. The mayor called a special meeting of the council to take action in the matter of submitting the question to vote again. The council failed to attend in sufficient numbers to make a quorum and thought the matter was blocked. The law provides for the submission of such matters on petition, and the mayor promptly circulated petitions and soon secured the required number of names. As the matter has to be published four consecutive weeks it was a narrow escape for the question. The coming election will be fought out on the question of a municipal plant.

The electric-light plant for West Liberty, Ia., has been completed and put in operation. C.

PERSONAL.

F. W. Vogel, lately superintendent of the Ohio Electric Construction company of Chicago, is now

signal engineer for the Railroad Supply company of Chicago.

J. Sterling Morton is to re-enter the field of journalism. He is to be editor of a new paper with the unique name of The Dynamo, which he will issue weekly at Nebraska City.

T. E. D. Ritchie, who has been for some time with Sargent & Lundy of Chicago, has gone to New York to take charge of the eastern office of the Fort Wayne Lamp company.

Stanley Green has resigned the western management of the Fuel Economizer company, after holding the position five years, and has formed a partnership with S. S. Howell, who was with the Fuel Economizer company for two years. The new firm will act as manufacturers' agents in Chicago, with the exclusive western agency for the American fuel economizer, made by Broomell, Schmidt & Co. of York, Pa.

ELECTRIC LIGHTING.

The Natchez Gas Light company of Natchez, Miss., will expend about $10,000 in improving and adding new machinery to its electric-light plant.

At last Monday's meeting of the Chicago City Council the mayor sent in a veto and an amendment to the ordinance granting the Consumers' Electric Light company an extension of time to lay its wires. The amendment requires the company to pay the city five per cent. of its gross receipts, and the ordinance, with the compensation clause, was passed.

ELECTRIC RAILWAYS.

Surveys have been made for about three miles of the electric street railroad to be built by the Jackson (Miss.) Railroad and Light company. Construction is to be begun at once.

A company has been incorporated with a capital of $150,000 to construct an electric railway from Cumberland, Md., through the mining region, 28 miles, to Westernport.

It is reported that the Raleigh (N. C.) Electric Railroad company has made arrangements to extend its trolley system and that the city authorities will assist in building the line.

Arrangements are being made for the proposed street railroad line on the Metaire road, in the suburbs of New Orleans. R. M. Wamsley is president of the railroad company.

In discussing the assertion that overhead trolley wires in city streets endanger the lives of horses, the Electrical Review of London says: "It takes precious little current, anyway, to kill a horse, and if public convenience is preferred the horses must either go off the streets altogether or take the risk. The average horse would, we think, prefer to take the one-in-a-million chance of being shocked to death rather than the one-in-a-hundred chance of being worked to death on a tramway in a couple of years."

A writer in the New York Times, in speaking of the commercial development of the electric street railway in this country in the last ten years, says that of the electrically operated street railways in this country in 1896, 25 roads showed gross receipts of over $1,000,000 each, while 17 others enjoyed gross receipts between $500,000 and $1,000,000 each. The same writer says that apprehension was felt a few years ago that the trolleys would cut into the business of the steam lines, and now the sounder judgment is that electricity will ultimately replace steam power upon interurban railways.

TELEGRAPH.

An ordinance has been introduced in the Chicago City Council granting permission to the Printing Telegraph News company to construct and operate in the streets and alleys and under the Chicago River, within the south line in Twelfth street, the west line in Ashland avenue, the north line in Kinzie street and the east line in Michigan avenue, a line or lines of wires or electrical conductors for the transmission of sound, signals and characters by means of electricity and a line or lines of pneumatic tubes. The franchise runs for 25 years and contains no compensation clause. John P. McGeorty is attorney for the company. He says the company has been operating for several years furnishing sporting news to its subscribers, and that now it desires to extend its service.

At the coming fast sending telegraphic tournament at the electrical exposition in Madison Square Garden, New York, in May, handsome medals or badges, with liberal cash prizes added, will be awarded to the victors. The events so far arranged will include: A message class for receivers, transmission 30 minutes, receivers to use typewriters of their selection; novice class, open to persons not having an official record, sending five minutes; championship class, open to all, sending five minutes, with prize [illegible]; ladies' class, free for all, sending five minutes; 240 word class, open to those not having an official record of 240 words or better, sending five minutes; 235 word class, open to all who have not an official record of 235 words or better, sending five minutes; 230 word class, open to all who have not an official record of 230 words or better, sending five minutes; 225-word class, open to all who have not an official record of 225 words or better, sending five minutes. An entrance fee of $2 will be charged. Thomas A. Edison is taking great interest in this tournament, as he always does in such affairs, and he will make a phonographic record of the best transmissions, noting the exact time of the revolution of the machine so that perfect reproductions can be made at any future time. The contestants will thus be enabled to have an exact record of their own work, which they can listen to whenever they feel so disposed.

TELEPHONE.

A telephone system is proposed at Griffin, Ga., and E. W. Coleman is mentioned as interested in the project.

At Dawson, Ga., telephone extension lines are being considered. B. D. Menser is actively identified with the movement.

A. S. Lindstrom of Willows, Cal., is building a telephone line from Willows to Elk Creek, Cal., connecting with the Sunset Telephone and Telegraph company at Willows.

J. C. Hubinger of Keokuk, Ia., announces that the City Council of Minneapolis has granted the Mississippi Valley Telephone company a franchise to erect and maintain a telephone exchange in that city. A canvass made before the franchise was asked for brought 4,000 five-year contracts with subscribers for telephones. The same company has also been granted a franchise in Muscatine, Ia., for an exchange there, and it will soon begin work on both of these exchanges. It also intends to extend its toll lines this season to quite a large extent, meeting and connecting with other independent systems.

POWER TRANSMISSION.

A syndicate of New York and Saratoga capitalists has purchased at a cost of $60,000 the land in the vicinity of Hell Gate Rapids on the upper Hudson, about seven miles above Glens Falls. The intention is to utilize the great water power at the place for an electrical plant. A dam and power house are to be erected, and with the electricity generated therein a railroad, to be known as the Saratoga Northern, running between Saratoga Springs and South Glens Falls, will be operated. This road will have branches to intermediate places and also to Glens Falls, Sandy Hill and Fort Edward.

There are good prospects that another canal will be built to divert a portion of the water of the upper Niagara River from its natural course, to be used for power and other purposes. This time Lockport, Niagara County, N. Y., hopes to benefit by the project, and recently the contract was signed by the mayor and city clerk on behalf of the city and by the presidents of the Niagara, Ontario and Lockport Power company and the Lockport Water and Electric company for a supply of 15,000,000 gallons of water daily for 10 years at an annual cost of $50,000. Lockport has always been lacking in a proper water supply, and it is authorized to enter into a contract for a supply by an act of the Legislature. The contract was made no doubt as an encouragement to the companies owning the canal and power franchises to enlist capital sufficient to carry out the project. The canal must be finished and water ready for delivery by May 1, 1904, or the contract will be without effect. At present the manufacturers of Lockport are dependent on the Erie canal for their power supply to a great extent, and this supply is very fickle, as at times the water is shut out of the canal, thereby forcing the plants to shut down or operate by steam. The canal it is proposed to build would have a length of about 20 miles, and probably tap the Niagara River between La Salle and North Tonawanda.

A bill has been introduced in the New York state Legislature providing for the incorporation of the Genesee Power company with a capital stock of $3,000,000, with power to increase to $12,000,000. Among the incorporators and directors are William A. Boland of New York, Cassius M. Wicker of the banking firm of Holins & Co., representatives of the Baring Brothers, New York; Theodore W. Myers, banker, formerly controller of New York city, and George H. Keller, capitalist, of New York. This company proposes to revive the Genesee River storage-dam project in a new form. Heretofore it has been advocated as a state work, but it is now proposed that private capital take hold of the scheme and develop it. It is understood that the water right owners and millers of Rochester are a unit in support of the bill, which provides for the building of a dam in the upper Genesee River, near Portage, and the consequent sale of water and water power. Portage is about 57 miles from Rochester. It is stated that one year when it was very dry the river for several months furnished only 5,500 horse power, while with a storage dam the minimum would be not less than 30,000 horse power. It is also thought that very material sanitary results would be accomplished in Rochester, not only by keeping clear the bed of the river from Main street to the Upper Falls, but also by increasing the flow of the lower river, now badly polluted by sewage.

ELECTRICAL SECURITIES.

The North Shore Traction company reports gross earnings for January of $98,864, an increase of $6,159 as compared with the same month of last year, and net $34,477, an increase of $10,006.

The New Orleans Traction company reports gross earnings for January of $107,222, an increase of $5,963 as compared with the same month of last year, and net $44,157, an increase of $12,930.

Application is to be made shortly to list on the Philadelphia Stock Exchange securities of the United Traction company of Pittsburg, $17,000,000 common stock, $3,000,000 preferred and $4,725,000 five per cent. bonds.

The Columbus Street Railroad company reports gross earnings for February of $47,601, an increase of $4,807, as compared with the same month of last year, and net $24,263, an increase of $1,487. For the two months ended February 28th the gross earnings were $101,389, an increase of $11,726, as compared with the corresponding period of last year, and net $52,861, an increase of $6,988.

MISCELLANEOUS.

The Crofton Storage Battery company of Chicago has been incorporated by Charles B. Stafford, A. C. Crofton and J. K. Pumpelly, with a capital stock of $25,000.

Caryl D. Haskins suggests that the amount of ash-producing material in coal may be determined by the use of the X-ray and the fluorescope. The density of the shadow of coal of unknown value may be compared with that of a standard specimen.

"How to Become an Electrical Engineer" is a problem that is occupying the minds of many young men to-day who are casting about for a profession. The subject is considered in the pamphlet issued by the Electrical Review Publishing company of New York, containing two essays on the subject and a list of colleges giving courses in electrical engineering.

The French town of Etampes has introduced an interesting novelty by replacing the recording secretary of the Municipal Council with a phonograph. Some of the members of the council objected to the innovation on account of the too great faithfulness of the apparatus in reproducing defective pronunciation and errors of speech, but the majority was in favor of making a trial.

Observations have been made recently, says the Scientific American, to determine the extent and cause of the extraordinary deflection of the magnetic needle which takes place over a vast tract of Central Russia. The line selected for observation was one of about 850 miles between Moscow and Kharkov. The widest aberrations are found to exist in the province of Kursk, the capital of which is about 600 miles south of Moscow. In the southeast portion of this province, about 150 miles south of Tim, the needle is deflected more than 96 degrees, and points almost due east and west instead of north and south.

The "war scare" seems to have stirred up the English government. A London correspondent says: "The consternation created at the time of Prince Henry's visit, when the German warships Deutschland and Gefion suddenly loomed out of the fog without having previously been sighted, has aroused the authorities to the necessities of taking additional precautions, and they are now erecting quick-firing guns and searchlights. At the entrance of Portsmouth harbor there will be a light powerful enough to sweep Spithead, and guns will be so placed that ships entering must pass under their muzzles.

TRADE NEWS.

The Western Electric company in advertising the Simplex tape offers to send samples free to those who desire to use it, stating that the recipients need not purchase until they are convinced of the superior merits of the tape.

The Keystone Electrical Instrument company has appointed W. R. Garton of Chicago agent for this territory, and the Chicago sales office will be in his charge. Similar arrangement has been made with William Kline & Co. of New York, dealers in miniature and decorative incandescent lamps.

The Warren Electric and Specialty company of Warren, O., manufacturer of anti-trust incandescent lamps, is keeping up its fight with vigor. The latest development is a reproduction of the first page of a circular sent out by a trust company, which the Warren company adroitly uses to its own advantage.

In order to provide funds to be used for the purchase of additional apparatus for manufacturing lamps and electrical specialties, the stockholders of the K. & W. company of Pittsfield, Mass., have voted to increase the capital stock. The demand for the Hardy lamp has been steadily increasing, and the K. & W. hangerboard is also proving popular.

The Armour Elevator, Chicago, recently started up a Ball engine, built by the Ball Engine company, Erie, Pa., for electrical purposes. The Eden Musee of Chicago has also installed for lighting a Ball en-

gine, and the Bristol Gas and Electric Light company of Bristol, Tenn., has installed a 200 horse power Ball cross-compound condensing engine built by the Ball Engine company.

Secretary and Treasurer Frank G. Scofield of the Bossert Electric Construction company of Utica, N. Y., called at the office of the Western Electrician last week. Mr. Scofield's trip to Chicago was partly to select a western representative, with the view of opening a branch of his business, with Chicago as a center. The Bossert company has already made itself felt in the West, but Mr. Scofield for a long time has felt the need of a personal representative on the spot.

The Electric Appliance company is anxious to emphasize the fact that it is agent for a commercially successful electric soldering iron. The company has now been handling the irons of the American Electrical Heater company for about two years, and in not a single case have these devices been unsatisfactory. The Electric Appliance company is willing to show its confidence in these goods by guaranteeing every iron it sends out to do its work in an entirely satisfactory manner.

The Davis & Egan Machine Tool company of Cincinnati, O., has just received an order through its Amsterdam office for several lathes, shapers and heavy screw machines, to be used by the Holland government. It has also received through its London office orders for lathes, drill-presses, planers and shapers for Greenwood & Batley, machine tool builders and government contractors at Leeds. Business in this country is also improving, the company having secured a number of large orders here in the last week.

President Charles M. Proctor of the Proctor-Raymond Manufacturing company of Buffalo, N. Y., visited Chicago last week. Mr. Proctor is pushing a line of electric bells that contain a number of valuable novel features. The Proctor-Raymond Manufacturing company has done excellent work in the matter of introducing its product throughout the United States, and Mr. Proctor is now on an extended business trip; after leaving Chicago he will work his way through the larger cities back to Buffalo.

On March 3d Judge Fish of Milwaukee refused to set aside the judgment obtained by the American Rheostat company of Milwaukee against the Cutler-Hammer Manufacturing company. The judgment was obtained before Judge Fish by default, and the court estimated the damages at $5,000, one-half the amount prayed for in the complaint. The Cutler-Hammer company made statements to its patrons, and patrons of the Milwaukee company, it is alleged, which were derogatory to the Milwaukee company. Circulars of the same import are alleged to have been distributed among the trade. The Cutler-Hammer company a short time ago made application to Judge Johnson to have the judgment set aside.

The Card Electric company of Mansfield, Ohio, has added quite an extension to its offices and is also making large extensions to its present shop and foundry. When these improvements have been completed the company will be in a position to handle orders with promptness, and the changes will also facilitate materially the building of the larger and heavier designs of electrical apparatus. These extensions are due to the fact that the company anticipates a greater output during this and the coming year than in the past. The Card Electric company has also issued under recent date a neat and handsome catalogue with illustrations and descriptive matter of new designs in direct-current slow-speed multipolar dynamos and motors, for both belted and direct service, and will be pleased to supply copies of it on application.

In about two weeks the Bullock Electric Manufacturing company will commence the erection of its new plant in Norwood, Ohio, about four miles from Cincinnati. The contract for the steel structural work has been let, and bids for the engines, boilers, etc., are now being received. This plant will consist of a large machine shop, brass foundry, pattern and office building and power house, and will have four or five times the capacity of the present Bullock plant. The company is ordering many new machine tools, and its shop will contain the finest tools in the market, as well as the latest electrical apparatus. In nearly all cases each tool will have a motor directly attached to it, reducing belting and shafting to a minimum. It is the desire of the company to make this a model plant, and it will no doubt contain many new and interesting features.

BUSINESS.

The Diamond State Tube company, Elsmere, Del., has recently put on the market a waterproof, fireproof tubing for electrical installation which is meeting with ready sale. This product is claimed to be superior to anything heretofore used and cheaper. Samples and prices may be had on application.

Huebel & Manger of Brooklyn are selling 50 per cent. more of their skeleton fire-alarm and signal bells than they did a year ago. This shows that the trade appreciates the fact that a bell used for such important purposes must be capable of doing every test. The Huebel & Manger bell has a good record of six years' duration and is fully guaranteed.

The Pennsylvania Line has placed in service on its night trains between Chicago and Cincinnati Pullman compartment cars, thus improving its already excellent accommodations between Chicago and the Ohio River. For space apply to ticket agents Pennsylvania Lines, No. 248 Clark street, Auditorium Hotel, No. 221 Michigan avenue, or Union Passenger Station, Canal and Adams streets, Chicago.

The Hunter Fan and Motor company of Fulton, N. Y., is making extensive preparations for the coming season's work. This company has made a specialty of prompt deliveries, and it is the intention that this season shall in no wise differ from the past in this regard. The company's '98 direct and alternating-current ceiling fans are now ready for delivery, and a large number of orders have already been placed.

The W. E. non-sparking brush has proven to be one of the best preventives of the disastrous sparking which so frequently interferes in the successful operation of a dynamo. It is now being used in almost every city in the United States. A circular giving regular stock sizes and price-lists of these brushes will be mailed by the Western Electric company to anyone desiring the information.

Steel gears and pinions form the subject of a small pamphlet, well illustrated and daintily printed, issued from the press of the General Electric company, under the title, "A Modern Gear Plant." It contains a description of the extensive plant which that company has established at the river works at Lynn for the exclusive manufacture of steel gears and pinions, and which has been equipped throughout with the most modern machinery. This pamphlet will be sent on application to any of the company's sales offices, one of which is found in every large city in the United States.

The Walker company will shortly install two six-pole, 100-kilowatt lighting generators in the Metropolitan Museum of Art in New York. The Presbyterian Hospital has also placed an order with the company for a 100-kilowatt generator and switchboard. A Walker alternator, three-phase, 60-cycle, for lighting and power has been purchased by C. Burkhart of Hudson, Wis., while the Los Angeles Traction company of Los Angeles, Cal., has ordered a 500-kilowatt railway generator of the belted type and a generator panel for the switchboard. Among the electric-railway equipments recently ordered from the Walker company may be mentioned 10 double 3 S equipments with type S controllers sold to the Erie Construction company for the Buffalo Traction company; three double 40 horse power equipments with S controllers, to Isaac A. Walker & Son for the Quakertown (Pa.) Traction company, and two double 3 S equipments for storage-battery motor cars to S. M. Fisher, for the Patton Motor company. The Walker company states that the type "S" solenoid-blow-out controller is the most popular one the company has ever placed on the market. The controller departments of its factories are turning out large numbers of the type S apparatus.

The Utica Electric Manufacturing and Supply company of Utica, N. Y., has recently organized a special department for repair work of all kinds. The principal feature is the repair of armatures, which can be handled up to any size. The company solicits business in this line from any portion of the United States, and will furnish estimates immediately upon any kind of work that may be offered. This department will be under the direct supervision of Herbert A. Abbe, who for six years was foreman of the armature room of the Eddy Electric Manufacturing company of Windsor, Conn. Special tools and equipment have been secured for this class of work. General Manager W. C. Baldis reports that the company has been very busy of late in general constructing work, and recently contracts have been obtained for the furnishing of a large number of isolated plants in northern New York and the Thousand Islands. A recent contract received from S. S. Spaulding of Buffalo, to equip his large private residence at Otsego Lake, was sought after by a number of electrical concerns. An order for a 500-light plant for Masonic Temple at Utica, the construction work for the new knitting mill and the Sherborn knitting mill of Utica, and also the contract for furnishing the lighting installation for the village of Oriskany, N. Y., where large Eddy machines will be used, will keep the Utica company very busy for the present.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued March 1, 1898

599,718. Plate for Accumulators. Wilhelm Majert, Grunau, Germany. Application filed August 19, 1897.

An accumulator plate comprising the bar having corrugations therein of the shape of the half of a cone when divided on the line of its axis.

599,742. Apparatus for Visible Signaling. Leopold Sellner, Vienna, Austria Hungary. Application filed March 28, 1896.

A signal light is provided with electrical appliances adapted to render it visible or obscure and an electric circuit including the appliances.

599,766. Insulated Railway Joint. Peter Clark, Philadelphia, Pa. Application filed May 21, 1897.

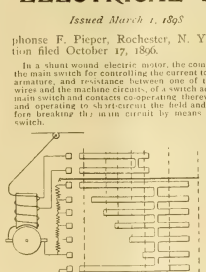
Two ties are connected by blocks of equal thickness halved into the ties, so that the upper and lower surfaces thereof will be flush with the upper and lower surfaces of the ties, two chairs are placed thereon, each of which has formed therewith a stay-plate, and means for securing the chairs and rails in place are provided.

599,789. Transformation of Alternating Currents into Direct Currents. Adolph Muller, Hague, Germany. Application filed July 30, 1897.

In the mode of transforming alternating into direct currents, electrically connecting a shunt circuit with the alternating current circuit before the interruption of the electrical connection between the latter circuit and a discharge circuit, maintaining the connection between the alternating current and shunt circuits during the period of interruption and generating in the shunt circuit a counter-electromotive force, which at any moment of the period of interruption will be substantially equal to the electromotive force of the alternating current, whereby at the moment of the interruption the primary circuit will be without current.

599,791. Electric Motor. Oscar H. Pieper and Alphonse F. Pieper, Rochester, N. Y. Application filed October 17, 1896.

In a shunt wound electric motor, the combination with the main switch for controlling the current to the field and armature, and resistance between one of the leading-in wires and the machine circuits, of a switch actuated by the main switch and contacts co-operating therewith arranged and operating to shortcircuit the field and armature before breaking the main circuit by means of the main switch.



NO. 599,806.

599,891. Toll-collecting Device for Telephones. Charles E. Scribner, Chicago, Ill. Application filed July 26, 1897.

The combination is claim 1 with a coin-chute provided with a socket for a coin, of a finger adapted to grasp the coin when in the socket, means for releasing the coin from the pressure of the finger and a signal-sounding device operated by the finger when released.

599,803. Rheostat. Sidney H. Short, Cleveland, O. Application filed May 14, 1897.

In a rheostat for street-railway motors, a spider having radial arms adapted to receive the resistance material in spiral convolute layers therebetween, and means for attaching the motor circuit terminals to such resistance material.

599,804. Method of and Means for Controlling Electric Motors. Sidney H. Short, Cleveland, O. Application filed May 19, 1897.

The method consists in maintaining constant or uniform accelerating current until the desired speed has been attained, and thereafter reducing the current, thereby maintaining a uniform speed.

599,805. Method of and Means for Controlling Electric Motors. Sidney H. Short, Cleveland, O. Original application filed May 19, 1897. Divided and this application filed October 21, 1897.

The method of controlling motors consists in varying the windings of the motor held to maintain a substantially uniform accelerating current, and thereafter reducing the motor current to a point such as to maintain a uniform speed.

599,806. Method of and Means for Controlling Electric Motors. Sidney H. Short, Cleveland, O. Original application filed May 19, 1897. Divided and this application filed October 21, 1897.

The method in this case consists in varying the relative connections of two or more motors to maintain a substantially uniform accelerating current, and thereafter reducing the current to a point such as to maintain a uniform speed.

599,807. Pneumatic Controlling Mechanism for Electric Railway Cars. Sidney H. Short, Cleveland, O. Application filed November 13, 1897.

A controller is provided for each car in a train, fluid pressure mechanism for simultaneously actuating the con trollers, and means mounted on each car of the train for controlling the fluid-pressure mechanism.

599,810. Alternating-current Motor. William Stanley, Pittsfield, Mass. Application filed May 9, 1896. Renewed November 17, 1897.

An inducing member is provided with a set of contiguous polar faces of one magnetic phase, and a set of polar faces of a different magnetic phase presented to the induced member so that the resulting fluxes are complanar, each of the sets containing poles of opposite signs.

599,815. Varipolar Motor or Dynamo. Henry H. Wait, Chicago, Ill. Application filed August 20, 1896. Renewed July 29, 1897.

A plurality of independent armature windings and separate commutators for the independent windings are described.

599,818. Electric Arc Lamp. Ernest P. Warner and Henry H. Wait, Chicago, Ill. Application filed March 16, 1897.

The arc lamp has a chimney of insulating material by which the lamp is supported; ducts therein are adapted to receive and protect the carbon or feed rod and the conductors leading to the lamp, and a hood or canopy is adapted to protect the insulating chimney from moisture.

599,828. Electric Railway. William M. Brown, Johnstown, Pa. Application filed October 7, 1897.

A traveling magnetic closer having a compound winding comprising a winding receiving a shunt current from the main circuit, and a second winding receiving a current from the main circuit only when the current is passing to the motors, in combination with an independent source of current supply, and means for passing current therefrom through the second winding when the main-circuit voltage falls abnormally.

599,832. Warp Stop-motion for Looms. Charles Crompton, Worcester, Mass. Application filed July 28, 1894.

A series of warp detectors is adapted to be sustained by the unbroken warp threads, and a support is required for the detectors, a contact into electrical engagement with which the detectors are moved by the breakage of their respective threads, an electro-magnet in circuit with the contact, an armature therefor, a stopping mechanism for the loom controlled thereby and including a rotatable shipper-shaft, mechanism operated by the electro-magnet to move the shipper-shaft slightly, and a spring to quickly complete the movement of the shipper-shaft to stop the loom.

599,862. Electrically Propelled Vessel. Daniel O'Flaherty, Kansas City, Mo. Application filed May 12, 1897.

A vessel is provided with electric motors mounted in casings and adapted to engage the extensions, the motors being in electrical connection with the pilot-house, and the vessel being provided with an electrical steering mechanism which is also in electrical connection with the pilot-house.

599,867. Telephone Transmitter. James H. Rogers, Bladensburg, Md. Application filed March 9, 1897.

In a telephone transmitter there is the combination with a fixed electrode, of a movable electrode mounted thereon and having a projection entering the fixed electrode to hold it in place on the latter, and an elastic conical or skirt-like sounding-board or target depending from the movable electrode

599,868. Electric Car Trolley. William H. Russell, Newcastle, Canada. Application filed April 18, 1896.

The block or frame is connected to the trolley arm to be movable laterally therewith.

599,880. Electric Arc Lamp. Christian Tepel, Bennett, Pa. Application filed December 31, 1896. Renewed January 27, 1898.

An arc lamp is provided with an electro-magnetic feeding mechanism and a vertically movable slotted tubular holder for the upper carbon, in combination with a mechanical feeding mechanism provided with a slotted tubular holder for the lower carbon, pivoted dogs having heads located within the tubes, a longitudinally adjustable connection between the two feeding mechanisms for effecting a positive differential feed, whereby the arc is maintained at the one point.

599,881. Magnetic Closer. Joseph N. Thomas, Johnstown, Pa. Application filed October 19, 1897.

A magnetic closer having an extended pole is adapted to supply a substantially continuous magnetic field throughout its length, and is composed of a plurality of sections insulated from each other.

550,891. Electric Contact Device. John L. Buchanan, Johnstown, Pa. Application filed February 4, 1897.

An electric contact device comprising a plurality of pairs of contact makers having upper flanges, each pair being adapted to surround the conductor, means for yieldingly pressing the flanges of the contact-makers of each pair together above the conductor, and a common frame upon which the contact-makers are secured.

599,892. Electric Regulator for Dynamos. William H. Chapman, Portland, Me. Application filed February 10, 1897.

The solenoid has a movable iron core, and is composed of four distinct coils of wire arranged to oppose each other and to balance each other's magnetic and mechanical action on the core, and to thereby neutralize each other's effects whenever an even number of them is in action, and to pull the core one way or the other when an odd number of them is in action, a set of electrical contacts arranged to open and close the electrical circuit through one of the coils and so unbalance the opposing force and thereby to cause the movement of the core, and a rheostat whose arm is arranged to be operated by the movement of the core.

599,910. Incandescent Electric Lamp. John T. Lister, Cleveland, O. Application filed October 2 1897.

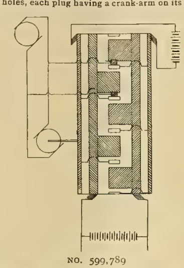
A bulb is provided with two filaments and two pairs of terminals the filaments being placed side by side, a base, and circularly shaped spring contacts therein, one of the contacts being shorter than the other, whereby the shorter contact will engage only one terminal at a time, and means for rotatably securing the bulb to the base.

599,913. Electric Motor. Edmund McNerney, Pittsfield, Mass. Application filed May 22, 1897.

A compound wheel is mounted upon the fly-wheel axle, and consists of insulating and non-insulating material, a shaft mounted on the frame, a double-pronged brush mounted upon the shaft, and means for projecting either prong against the compound wheel and for holding the same in contact therewith.

599,918. Motor Casing. Sidney H. Short, Cleveland, O. Application filed February 16, 1897.

The two-part casing has the field cores on its inner surface, and in its ends bearings for the armature shaft, both of the ends of the lower half of the casing having in line with the end of one of the field cores near its lowest point inspection holes and removable screw plugs for closing the holes, each plug having a crank-arm on its outer end.



NO. 599,789

599,929. Quick-break Switch. Harry P. Davis, Pittsburg, Pa. Application filed July 22, 1897.

A quick-break switch comprising a pair of stationary jaw terminals and a pair of spring plates or strips, the space between which is contracted at or near their outer ends, in combination with a blade having a tongue extending along its inner edge and provided with a head at its free end which engages with the inner faces of the spring plates or strips.

599,930. Switch for Electric Circuits. Harry P. Davis, Pittsburg, and Ernest F. Harder, Wilkinsburg, Pa. Application filed October 28, 1896.

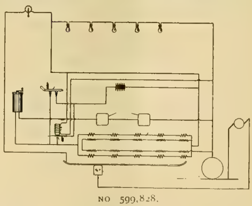
A switch for electric circuits comprising a stationary jaw terminal and a movable blade having spring plates or washers riveted to its sides, the outer side faces of which make contact with the stationary jaw terminal.

599,931. Electric Arc Lamp. Harry P. Davis, Pittsburg, and Frank Conrad, Wilkinsburg, Pa. Application filed August 22, 1896.

A dash-pot for arc lamps comprising a cylinder and a plunger, one of the parts being stationary and the other longitudinally movable, in combination with a yielding, resilient cushion for the stationary member which permits lateral movement of the member from its normal position, but tends at all times to restore it to such position.

599,932. Method of and Apparatus for Regulating Electric Motors. Budd Frankenfield and Dugald C. Jackson, Madison, Wis. Application filed January 28, 1897.

The method described of varying the speed of a multipolar motor consists in weakening and strengthening the magnetomotive force due to the coils exciting one or more of the poles, while leaving the magnetomotive force due to the coils exciting one or more of the poles unchanged.



NO 599,828.

599,940. Non-synchronous Electric Motor. Benjamin G. Lamme, Pittsburg, Pa. Application filed April 30, 1894.

A rotary field motor is described, having a primary member provided with a distributed winding located beneath the surface of the core and in proximity to the adjacent surface of the secondary member, the coils of the winding being superposed and severally embracing a peripheral core space which differs from that obtained by dividing the whole circumference by the number of poles.

599,941. Direct-current Electrical Machine. Benjamin G. Lamme, Pittsburg, Pa. Application filed May 8, 1896.

A field magnet having inwardly projecting pole pieces is provided with relatively narrow magnetic pole shoes which project laterally from the pole faces, and serve to increase the width of the fringe of the magnetic field.

599,942. Inductor Dynamo. Benjamin G. Lamme, Pittsburg, Pa. Application filed July 12, 1897.

A magnetizing coil is provided with a magnetic circuit having a relatively wide air-gap and a relatively narrow air-gap, in combination with a set of generating coils adjacent to the wide air gap.

599,943. System of Electrical Distribution. Benjamin G. Lamme, Pittsburg, Pa. Application filed September 18. 1897.

Means are provided for varying the electromotive force of a work-circuit in accordance with changes in load comprising an auxiliary generator having a series field-magnet winding and a separately excited winding, in combination with an exciter for the latter having a field-magnet winding which is traversed by the feeder current.

599,947. Electrically Propelled Vehicle. Philip R. Salberg, Pittsburg, Pa. Application filed February 5, 1896.

The vehicle is provided with an overhead trolley, and means for simultaneously applying the brakes and pulling down the trolley when the latter leaves the supply conductor, the means being controlled by the upward movement of the trolley above the conductor.

599,954. Switch for Electric Circuits. Gilbert Wright, Wilkinsburg, Pa. Application filed September 18, 1897.

A double-throw switch comprising stationary socket terminals, co-operating plungers and a pivoted operating lever having arms provided with cams for engaging and actuating the plungers alternately in opposite directions.

599,975. Portable Electric Lamp. Leonard Paget, New York, N. Y. Application filed July 8, 1897.

An electric lamp consisting of a case comprising two parts of conducting material insulated from each other and covered with external insulation, a lamp supported upon the case and electrically connected thereto, and a battery within the case, one of its terminals being in engagement with one part of the case, and the other adapted to be connected with the other part thereof by means of a movable circuit closer.

600,037. Weighing Machine. Francis H. Richards, Hartford, Conn. Application filed July 8, 1897.

The weighing mechanism described embodies a load receiver provided with a closer, a supply conveyor, driving mechanism for the supply conveyor, the driving mechanism including an electrical motor, an electric circuit embodying a device for governing the action of the motor, and a controller in the circuit and in position to be actuated by the closer, thereby to effect the operation of the device which governs the action of the motor.

600,057. Rheostat and Electric Heater. Henry P. Ball, Brooklyn, N. Y. Application filed October 30, 1897.

The ribbon-like conductor is disposed edgewise between two plates, and there is a layer of adhesive material on each plate in which the conductor is partially embedded and by which the conductor is attached to the plates.

600,058. Flexible Electric Conductor. Antoine Bournonville, Philadelphia, Pa. Application filed November 20, 1897.

A flexible electric conducting cord having a single central section and two or more terminal sections at one end, a fabric covering for the cord extending continuously over the single section and the terminal sections.

600,063. Strain Insulator. Henry Carmichael, Malden, Mass. Application filed June 13, 1895.

This strain insulator is composed of interlocking metallic members, an interposed body of insulating material incompressible at substantially the temperature and tension of use specified, an enveloping mass of insulating material compressible at the temperature and tension of use, and an inclosing jacket for the compressible insulating material.

600,073. Telegraph Cable. John J. Hall, Slough, England. Application filed October 4, 1897.

An electric telegraph cable is composed of a plurality of conductors, each provided with a wrapping of a netted textile fabric secured thereon by a spirally wound textile thread or yarn, the conductors being laid in a bunch in the form of a cable, and a textile cord wound spirally around the whole.

600,088. Current Collector for Dynamo-electric Machines. George W. Nell, Philadelphia, Pa. Application filed February 23, 1897.

In a current collector for dynamo-electric machines the combination is described of the armature coils, current distributers, one or more magnets located above the collector, levers rotating with the armature and controlled by the magnet or magnets, and contact devices operated by the levers, whereby the connection of the opposite ends of the armature coils with the current distributers will be effected at the proper time, and both connections will be made at the top of the collector.

600,092. Electrically Operated Hoisting Machinery. Alton J. Shaw, Muskegon, Mich. Original application filed May 6, 1893. Divided and this application filed January 16, 1894.

Claim is made for the combination with trolley and with hoisting beam, tongs carried by the beam, motor for actuating the tongs, insulated conductors extending lengthwise of the beam and connecting with the motor, brushes or contact pieces carried by the trolley and arranged to maintain contact with the beam under varying adjustments of the latter, and a switch also carried by the trolley and serving to control the supply of current to the motor.

600,101. Supply System for Electric Railways. David Urquhart and Frank Wynne, London, England. Application filed February 25, 1897. Patented in England January 25, 1896.

In apparatus for supplying electricity to electrically propelled vehicles there is described the combination with switches for connecting a main conductor with successive road contacts, of electro-magnetic switch-operating devices, each having its winding in connection with a condenser, and a traveling alternator adapted to complete the circuit of the successive electro-magnetic devices through the corresponding condensers.

600,112. Electric Switch. James J. Flint, Denver, Colo. Application filed February 16, 1897.

The first claim is given: In an electrical switch, the combination with an insulating base, a cap-plate and push-buttons, of a lever-like circuit-closing arm adapted to be actuated by the push buttons, a support attached to the base and upon which said arm is fulcrumed, a roller attached to one extremity of said arm, a keeper also pivoted on said support and located adjacent the roller extremity of the arm, said keeper carrying a roller adapted to engage the roller of the said arm, and a coil-spring connecting the keeper with the stationary support, and suitable contacts which the circuit-closing arm is adapted to bridge.

Western Electrician.

EVERY SATURDAY.

Vol. XXII. CHICAGO, MARCH 19, 1898. No. 12

Snoqualmie Falls Transmission.

Work has been begun on an important power-transmission plant to connect Snoqualmie Falls, in the Snoqualmie River, state of Washington, with the cities of Seattle and Tacoma. Snoqualmie Falls is a very impressive cataract, as will be seen by the accompanying picture, with an unbroken fall of 270 feet. It is about 25 miles east from Seattle and about 35 miles northeast from Tacoma. At low water the power in sight is estimated at 20,000 horse power, but this can be largely increased at comparatively small expense by the construction of a dam, creating a storage reservoir, for which the topography of the country is well adapted.

The Snoqualmie Falls Power company (capitalized at $500,000), which has the work in hand, proposes to install an initial plant capable of delivering 5,000 electrical horse power at the cities named. It will sink a shaft at the edge of the river, about 350 feet above the brink of the cataract, to a depth of about 250 feet. This shaft will be eight by 25 feet in horizontal dimensions and will be large enough to pipe down water capable of exerting a force of 10,000 horse power. The type of water-wheel has not been decided upon, but there will probably be three or four large units of about 2,000 horse power each. The water-wheels will be directly coupled to large generators, probably of the three-phase type, and it is likely that two dynamos will be attached to each water-wheel, one on each side, to make a generating unit. An interesting feature of the plant, as now proposed, is the fact that the generators as well as the water-wheels are to be placed in the cavity at the base of the shaft. The entire power plant, with its attendants, will thus be 250 feet below the surface of the ground above the falls. Access to this subterranean plant will be gained by an elevator in the shaft. A short tail-race will discharge the water into the lower level of the river.

Step-up transformers on the surface of the ground will raise the electromotive force of the current from the generators to a line potential of about 16,000 volts. At this pressure the current will be transmitted over pole lines to Seattle and Tacoma. At a distance of about 20 miles from the power plant the main line branches, one set of wires going to Seattle and one to Tacoma. The pressure will be reduced in sub-stations in the cities, and the power will be sold for various industrial purposes. The state of Washington produces a large amount of coal, but it is not of such good steaming quality or as cheap as that of the middle West, so that there should be a good demand for electrically transmitted water power at a cheaper price.

A number of Chicago gentlemen are concerned in the project. William T. Baker, ex-president of the Board of Trade, is interested in the company; Thomas T. Johnston is the chief engineer, and Sargent & Lundy are the electrical engineers.

SNOQUALMIE FALLS.

Surveys have been made for a four-mile extension to the Shamokin (Pa.) and Mount Carmel Electric Railway company's system. The proposed line will be constructed this summer and will extend from Mount Carmel to Locust Gap and thence to Locust Dale. At the latter place it will connect with the line of the Schuylkill Traction company, thus affording a continuous trolley line from Shamokin to Shenandoah and Mahanoy City.

Electrical Communication with Coast Defenses.

In a letter addressed to the secretary of war, Gen. A. W. Greely, chief signal officer of the army, again calls attention to the need of electrical communication with fortifications and other coast defenses. He says:

"The estimate of $20,000 for cables to connect electrically the fortifications in the harbors of New York, Boston and Philadelphia has been omitted from the sundry civil bill as reported by the House of Representatives. The chief signal officer would be derelict in his duty did he not call the attention of the secretary of war to the necessity of urging upon the Senate such an appropriation. For seven consecutive years the chief signal officer has unavailingly recommended the importance of this matter, reciting the fact that some of our most important defenses can only be reached by messenger.

"The destruction of the military cables between Alcatraz, Angel Islands and the mainland long since left the fortifications in San Francisco isolated and entirely unconnected electrically, and Fort Warren in Boston harbor is also without reach by telephone or telegraph. In New York harbor it is true that several posts can communicate with each other over circuitous commercial routes, but such complicated methods, inadequate in peace even, would inevitably break down in case of actual hostilities.

"These estimates have been recommended both by you and former secretaries of war, have been repeatedly urged as military necessities by the commanding generals of the departments affected, and have been heartily approved by the commanding generals of the army.

"Never more than to-day have time and co-operation been more noted elements of strength, whether in the industries of peace or the art of war. In the business world the most acute minds of the century are applying themselves to the development of speedy and increased communication, especially through electrical devices, and the failure of any country to utilize in this direction the highest inventive skill must materially lessen its chance of success in war. In every other country of the world the entire system of harbor defenses for each port is connected electrically, so that not only is intercommunication and the transmission of orders constantly maintained, but the fire control and the direction of the defense rest under one master mind.

"It must seem hardly credible to either business men or to experts that Congress after authorizing a system of coast defenses to cost millions of dollars should for years refuse to connect the military forts around the great cities of New York, Boston and San Francisco, either electrically or telephonically. In critical emergencies, such as arise in all defenses, military operations at these points would, under existing conditions, be necessarily conducted without concert or unison, thus needlessly jeopardizing lives by the thousands and property to the value of hundreds of millions of dollars.

"The present situation is parallel to that which would exist if our great cities, after spending tens of thousands of dollars in thoroughly establishing a fire department, should refuse to install therewith an electrical signal system and insist that alarms of fire should be sent either by messengers or by the nearest commercial telegraph line."

A late press dispatch states that General Greely has been given authority by the secretary of war to proceed without regard to ordinary restrictions in establishing rapid telegraphic connections between the sea-coast fortifications. It will not be necessary, therefore, to invite proposals for furnishing supplies and to follow the ordinary methods of procuring the telegraph material and doing the work. The rather extraordinary authorization was conferred upon General Greely after the forcible presentation given above. It is shown that even in New York harbor, where the War Department has devoted its best energies to the perfection of the fortifications, it requires three-quarters of an hour to pass a message from one battery to another. Fort McHenry, Baltimore, is worse off; while, strange as it may seem, the only method of communicating between the national capital and its most important defensive work, Fort Washington on the Potomac, is by means of a messenger.

The city of Higginsville, Mo., has sold a franchise to an independent telephone company, and it is expected that an exchange will be built in that city shortly.

O. O. Wiegand, manager of the Northeastern Wisconsin Telephone company of Shawano, Wis., announces that the company will extend its line from Angelica to Green Bay, Wis. Other extensions are also contemplated.

Protecting Inlet Canals at Niagara Falls.

By Orrin E. Dunlap.

At this time of year, when the great ice fields in Lake Erie are breaking up, immense quantities of ice pass down the Niagara River, requiring the power companies to be especially watchful of the water service through their canals. When the wind brings the ice of the lake toward the entrance to the Niagara River, it is remarkable what an immense amount of the ice enters and passes down stream to the falls. It is recorded in history that 50 years ago, on March 29th, this flow of ice was so great at Buffalo that it blocked the entrance to the river, so that for several hours no water passed in from the lake, and the great Falls of Niagara went dry for hours. Many are the stories told of the strange spectacle and of the weird sights that then presented themselves to the view of the residents of the Niagara locality of that day. Never since, however, has anything quite like that happened and the flow of water has been constant. Every winter the ice lodges in great fields on the bars in the upper river, but this has not served to interfere with the water supply of any of the great turbines.

It will be recalled that the entrance to the inlet canal of the Niagara Falls Power company is directed down stream in order to avoid the ice difficulty and also to protect it from catching drift of any kind coming down the river. In addition to this the entrance is protected by a timber boom resting against iron piers fastened to the rocky bottom of the canal. This boom is an efficient protector of the canal from ice and all kinds of drift, the confidence in its service being well displayed by the fact that the pulp wood for the big mill of the Niagara Falls Paper company floats down outside of it to the point where it is taken from the water and transferred to the mill yard. Last summer nearly 50,000 cords of this wood so floated by the boom and but a few small sticks entered the canal. Its service is portrayed in the accompanying illustration, Fig. 1, which shows the boom and the iron piers at the entrance to the canal. The service this boom performs in summer is repeated in the winter time, with the exception that in winter the great ice floes are warded off and guided in their course to the falls, there to make the plunge over the precipice and possibly later on to become a part of one of the wondrous ice-bridge formations for which Niagara is famous. Incidentally it may be remarked that this point on the upper Niagara is one of the well patronized bathing places at the Falls during the summer time, the boom affording an excellent resting place as well as a point from which to dive. Racks placed in front of the inlets to the penstocks still further protect the turbines from injury from floating substances.

The entrance to the Niagara Falls Hydraulic Power and Manufacturing company's canal is also protected by a boom in winter, as is shown in Fig. 2, which is slightly lowered at one side to show the direction of the flow of the river. This point on the canal is known as Port Day, and in the summer the boom is removed from the entrance and stored close to the side wall. Its principal use is to keep the floating ice out of the canal. As this canal is 4,400 feet long, more or less ice forms in it, also in the canal basin, but since it has been deepened, the ice seldom gives trouble.

The Hunter Patents of December 21, 1897.[1]

By A. Miller Belfield.

Considerable interest was excited by the appearance in the Official Gazette of December 21, 1897, of three patents to Rudolph M. Hunter of Philadelphia, Pa., for "Improvements in Electrical Transmission of Energy." These patents involve the use of transformers, or, it may be said, the induction of currents for local circuits from high-tension circuits by the use of transformers, and contain claims which appear at first sight to be broad, and perhaps even generic or basic.

Those who follow the development of electrical inventions by glancing over the Gazettes as they are issued were very much interested by the appearance of these patents, and curious to know what effect, if any, they might have upon the electrical industries already organized and employing transformers in the electrical transmission of energy. Those who were immediately engaged either in the use or the manufacture and sale of transformers were no doubt startled by the appearance of these patents, and very likely were more or less anxious as to whether or not the issue of these patents made them infringers of patents, by making or using what had been so generally used so long as to afford good ground for the belief that it was common property.

Some discussion has been indulged in regarding these patents and their status in electrical industries, and I am told there have appeared some articles implying that there existed a relation between these

FIG. 1. PROTECTING INLET CANALS AT NIAGARA FALLS.

Hunter patents and the Tesla patents for electrical transmission of energy, and intimating that they subordinated the Tesla patents.

With the hope of throwing some light upon these questions, I have taken up the consideration of the Hunter patents. I shall first consider the inventions and claims of the patents; next, the breadth or interpretation to which their claims seem entitled in view of the inventions they set forth, and finally what bearing, if any, they may have upon the present electrical industries.

These three patents are No. 596,041, which I shall term Patent A; No. 596,042, which I shall term Patent B, and No. 596,002, which I shall term Patent C. Patent A is assigned to George W. K. Stephens of Philadelphia, Pa., and is the outcome of a divisional application filed October 4, 1889, of an original application filed February 23, 1883. Patents B and C are both assigned to the General Electric company of New York. Both of them also are the outcome of divisional applications: that of Patent B being filed April 20, 1892, from an original application filed June 18, 1887, and that of Patent C being filed July 28, 1891, from an original application filed November 9, 1887.

First, with reference to No. 596,041, or Patent A. This patent shows diagrammatically two forms or arrangements of an apparatus for carrying out the invention which it sets forth. In the first of these (see Fig. 1) there is shown a transmitting station A and two receiving stations B and C. At the transmitting station A an undulatory current is generated in a local circuit 1, including a local battery 2, by speaking to or otherwise actuating a telephone transmitter 3, included in such local circuit. The undulatory current thus developed actuates an electro-magnet 4 included in the local circuit 1, and thereby causes to vibrate an armature 5 which is included in the line circuit 6 and which has its free end arranged opposite the pole of the thus variably energized electro-magnet 4. This armature 5, in vibrating, presses with greater or less force against a carbon block 7, which is likewise included in the line circuit 6, and thereby varies the resistance of such circuit so that a current which is generated in a battery 8, included therein, and which would otherwise be constant and continuous, becomes undulatory. This undulatory line current, upon arriving at the first receiving station B, passes through the fine wire or primary coil 9 of a transformer or induction coil D, and thereby induces a corresponding undulatory current in the secondary 10 thereof. The undulatory current thus induced, together with the current from a local battery 11, which augments it, actuates a telephone receiver 12 arranged in a local circuit 13 which includes the local battery and the secondary of the transformer, and also variably energizes an electro-magnet 14, likewise included in the local circuit 13. The electro-magnet 14, so variably energized, vibrates an armature 15, included in the line and resting upon a carbon pencil 16, and thereby varies the resistance in the line in a way which is said to "augment the currents flowing in the line, greatly increasing the inductive effect and hence the currents set up in the local circuit."

The undulatory current of the line upon arriving at the second receiving station C likewise traverses the primary 9a of a transformer D' located thereat, and in like manner induces a secondary current in a local circuit 13a, including the secondary 10a of the transformer D'. The arrangement of this second receiving station C is similar to that of the first mentioned receiving station B, with the exception that the vibratory armature 15, which presses upon a carbon pencil 16, so as to vary the line resistance, and which is actuated by an electro-magnet 14 at the first station, is actuated by the induction coil or transformer D' itself at the second station.

In the apparatus of the second system of this patent, a generator is employed as a means of producing the line current, instead of a battery, as in the first-mentioned system, and but one receiving station is shown, instead of two, as in the first instance. At the receiving station the line is connected in series with the fine wire or primary of a transformer, and at the receiving station no telephone receiver is shown in the local circuit, but instead, the specification states that any transmitting device may be used.

Thus it will be seen that the patent shows and describes an apparatus involving a line or circuit extending between a transmitting and a receiving station, means for developing therein a constant and continuous current, means at the transmitting station for varying the line resistance, so as to make the constant current undulatory, and at the receiving station a transformer or induction coil having its fine wire included in the line, a local circuit including the coarse wire or secondary of the coil, and a translating device included in the local circuit. The patent contains seven claims, six of which embrace more or less broadly the combination of devices above enumerated, while the seventh covers the method of transmitting electrical energy involved in the operation or employment of such combination, or an equivalent one.

Next, with reference to Patent B (see Fig. 2), a constant-current generator 1 is employed to develop a current in a line circuit 2, extending between a transmitting station A and two receiving stations B and C. This current is automatically interrupted so as to produce an interrupted, intermittent or broken current. In one arrangement of the invention it is interrupted at the receiving stations by means of common magnetic make-and-break devices, while in the other arrangement it is interrupted at the transmitting station by a rotary interrupter on the shaft 3 of the dynamo 1, as shown in Fig. 2. This interrupted or intermittent current is fed to the primaries or fine wire coils 4, 4, of transformers D, D, at the receiving stations B and C, and when thus fed operates to induce alternating currents in the secondaries or coarse wire coils 5, 5, thereof. The currents thus induced are utilized for translating devices, such as lamps, which are arranged in local circuits 6, 6, at the receiving stations B and C.

This patent, therefore shows and describes apparatus involving a line circuit extending between a transmitting station and one or more receiving stations, a constant-current generator which can develop current in the line circuit, means for interrupting the constant current so as to produce an interrupted or intermittent current, induction coils or transformers at the receiving stations, and local receiving-station circuits, including translating devices, such as lamps. The claims, seven in all, of which six are for the combination of devices above enumerated, more or less broadly expressed, while the remaining seven are for the method of transmitting and utilizing the electrical energy involved in the use of the apparatus comprising such combination, or an equivalent one.

Next, with reference to patent C (see Fig. 3). A generator 1 is employed to develop a current in local circuit 2 at the transmitting station A. This generator may be either an alternating-current ma-

1. Read before the Chicago Electrical association, March 11, 1898.

chine or a direct constant-current machine. In the latter case the current is either broken or interrupted, or is reversed; in either case the result is the production of a current serviceable for induction purposes. The current thus produced traverses the secondary or coarse-wire coil 3 of an induction coil D, situated at the transmitting station A, and thereby produces a current higher in potential than the current of the machine. This high-potential current is transmitted through a line circuit 4 extending from the transmitting station A to one or more receiving stations, such as B and C, at which latter it is transformed to lower potential currents by means of step-down transformers E, E. The lower potential receiving station currents thus produced are employed in part for translating devices, such as lamps, arranged in local circuits 5, 5, and are in part re-transformed into high-potential currents by means of step-up transformers F, F, likewise arranged in the local receiving-station circuits 5, 5.

This patent, then, shows an apparatus involving a line circuit extending from a transmitting station to one or more receiving stations, means for developing therein higher potential currents available for induction purposes, one or more step-down transformers which utilize the line current for producing receiving-station currents of a potential lower than that of the line current, a corresponding number of local receiving circuits which receive the low-potential currents thus induced and a corresponding number of step-up transformers which retransform the induced receiving-station currents into high-potential currents at the different receiving stations.

The patent has two claims which these devices more or less broadly set forth.

In brief, such are the Hunter patents. There now arise the questions as to their validity and their interpretation, if valid.

Inasmuch as they have not been adjudicated by a court of last resort, any opinion relating to these questions must, of course, be mere speculation. And as I have not been able to examine the file wrapper and contents of these patents and the art prior to their dates of application, what I have to submit upon these questions must be only such observations as can be based upon the patents themselves.

In these observations I shall refrain from expressing any opinion as to the validity of the patents either for lack of novelty or for lack of invention, although these questions are, of course, open in the present instance, and are by no means inconsiderable. But I shall not discuss them, because, as I say, I have not investigated the prior art, and they depend directly upon it for their determination.

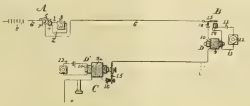


Fig. 1.

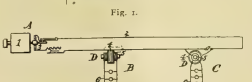

Fig. 2.

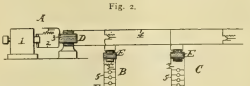

Fig. 3.

THE HUNTER PATENTS OF DECEMBER 21, 1897.

Neither shall I consider the question of inoperativeness of the devices of the patents as a ground for disputing their validity, although there exists in them some few things which seem to afford a basis for assertions to that effect. For instance, it seems doubtful to me that the electro-magnet 14, shown in Patent A, included in the local circuit 13 at the receiving station B and variably energized by the induced current thereat, will vibrate its armature 15 so as to produce vibrations in the line resistance corresponding with those produced in the line circuit 6 at the tran-mitting station A, because of the lag of the induced current behind the inducing current. This lag may be such as to cause the variations produced in the line resistance by the receiving armature to fail to correspond to the undulations of the line current to an extent to practically counteract such undulations. But I shall pass over these questions of novelty, invention and operativeness and attempt to point out what seems to me the construction to which the claims of the patents are entitled, assuming them to be good and valid.

Obviously, in their broadest conception, Patents A and B disclose the combination with a line circuit extending between a transmitting and a receiving station of means operable at the transmitting station for developing in the line currents which can be utilized for induction purposes, and at the receiving station means for transforming the line-inducing current into a current of different potential, and a local circuit which receives this current of different potential and is provided with translating devices adapted to utilize it.

The question undoubtedly is, What scope or breadth is to be given to the means for producing the line current which is serviceable for induction purposes? or, in other words, whether or not the patents can be so construed as to include any and all means for producing a current serviceable for induction purposes, or whether they are to be limited to the precise means they illustrate and describe.

The first six of the seven claims of Patent A, or, in other words, all of the apparatus claims of that patent, have their means for producing the line-inducing current limited to means for producing a current of alternately rising and falling potential, or alternately varying potential, or alternately increasing and decreasing potential, the different terms being used in different claims. The means illustrated and described by Patent A for producing the current which the specification terms a current of alternately rising and falling potential comprises, it will be remembered, a producer of a constant current, such as a primary battery, or a continuous current generator and means for varying the line resistance so as to render the current from such battery or generator undulatory, such means, for example, as a carbon pencil and a vibratory armature making contact therewith, in combination with an electro-magnet included in a local circuit at the transmitting station and variably energized by the actuation of a telephone transmitter, likewise included therein.

All of these six claims, except the fifth, are further limited by a more or less specific reference to this apparatus: the first to means to produce and maintain a continuous current and means to convert it into high-tension currents; the second to a variable resistance; the third to a source of electricity of one sign, and the sixth to a source of positive electricity; and the fourth to a main electric generator and means for operating it without interrupting the current so as to vary the potential, etc. These claims are, of course, limited to the devices which they enumerate. The fifth claim, however, is limited only by the term "alternately increasing and decreasing potential."

The claim is as follows:

5. A line conductor conveying currents of alternately increasing and decreasing potential, a series of local circuits, and corresponding induction coils, each of which has its fine-wire coil energized by the current in the same line conductor, and separate local circuits, each connected with the coarse-wire coil of the corresponding induction coil.

In terms it is broad enough to cover or include a line conductor carrying any variety of current having an alternately increasing and decreasing potential, whether produced by the apparatus shown in the patent or not.

But as the patent neither shows nor describes any other apparatus for producing a line current available for induction purposes, nor contains any suggestion that any other apparatus can be used therefor, there may arise some question as to what it can be considered to cover.

In view of the tendency of the courts to construe claims pretty closely to the apparatus shown in the patent, in the absence of extenuating circumstances, the expression "alternately increasing and decreasing potential" of this fifth claim may be construed by a court as meaning a direct or uni-directioned (as opposed to a true alternating or reversing potential) continuous, undulatory current, such as that produced by the apparatus set forth in the patent; and the claim therefore may be construed so as to cover apparatus for producing such a direct, continuous, undulatory current, and such apparatus only.

Claim 7 of this patent, which is the method claim thereof, is broader than the six apparatus claims, and contains no limitations as to the style of inducing current generated in the line. This claim is as follows:

"The method of transmitting electrical energy consisting in transmitting an electric current of high tension and small volume over a line circuit, and at one or more places on the line circuit, producing, by means of induction, currents of low tension and relatively large volume, and supplying said low-tension currents to one or more translating devices in said local circuits."

This claim, in its terms, includes the method of transmitting currents which are serviceable for induction purposes, transforming them into currents of relatively low tension and large volume, and utilizing the induced currents in local receiving-station circuits, irrespective of the style of line currents which cause the induction and irrespective of the style of induction apparatus employed at the receiving station. It is barely possible, however, that a court, instead of giving it a construction as broad as its terms, may construe it as covering only the method of inducing currents at the receiving station by means of uni-directioned undulatory line currents, as is done by the apparatus of the patent.

All of the claims of Patent B, except the sixth and ninth, contain qualifying terms limiting such of them as are apparatus claims to means for producing what is called a "maintained and practically uniform" current in the line circuit, and limiting such of them as are method claims to the generation and transmission of such "a maintained and practically uniform" current.

Just what the patentee meant by the term "maintained and practically uniform," I confess I am unable to say. Possibly it is meant to indicate that the series of current impulses follow each other in regular succession and correspond to one another in size and character, as would result from generating them by a dynamo-electric machine, in contradistinction to the current impulses which are produced in the apparatus of Patent A, as a result of intermittently or occasionally speaking to a telephone transmitter, and which consequently are irregular or fitful in succession, or even disconnected or intermittent, and are dissimilar or non-uniform in size and character.

This view is submitted only as a suggestion, however, and with not much assurance that it is the correct one. Very likely an examination of the record of the case would show some other meaning was intended. If its import is such as I have suggested, these claims, in their terms, cover or include means for generating, or the generation of, according as they are apparatus or method claims, any variety of current involving a regular series of similar or corresponding impulses. In such case, I take it that they, in effect, include any style of inducing current generated by a dynamo electric machine, for the

FIG. 2. PROJECTING INLET CANALS AT NIAGARA FALLS

reason that regularity in the succession of impulses, and correspondence in size and character thereof, are characteristics of a dynamo-generated inducing current, as opposed to a current generated as a result of the action of a telephone transmitter or like irregularly acting device.

If the meaning of the expression "maintained and practically uniform" is not such as I have suggested, these claims are limited in accordance with the interpretation given to it.

Claims 3 and 4 further characterize the currents of high tension as being alternating currents. As no apparatus is shown for generating what is a true alternating current, this expression, if it does not invalidate the claims altogether, must be considered as intending to describe a pulsatory current, that is, a current which alternately exists and does not exist.

Claims 6 and 9, as I have said, are not limited to the use of "maintained and practically uniform" currents. They contain no limitation upon the style of current generated or the means for generating it; but are respectively, the one for the method of transmitting electrical energy in a line circuit and of utilizing it to induce local currents at receiving stations, and of regulating the line current so as to vary all the currents in the local circuits simultaneously, and the other for apparatus by which this method can be carried out. In terms they are broad enough to include any and all varieties of apparatus for methods of generating currents serviceable for induction purposes, and for regulating the line currents so as to vary all the currents in the local circuits simultaneously.

Like claims 5 and 7 of Patent A, all of the claims of Patent B may not be given an interpretation as broad as their terms, but may, so far as anything now known is concerned, be limited to the apparatus set forth in the specification of the patent.

To summarize, it appears that these patents A and B, in their broadest conception, disclose means for generating and transmitting currents serviceable for induction purposes, means for transforming them into currents of different potential, local receiving-station circuits and translating devices for using these induced currents, and also disclose the method involved in the use of such apparatus; that Patent A contains a method claim as broad in terms as the disclosure and an apparatus claim limited only by the expression "alternately increasing and decreasing," applied to the inducing current, and that Patent B has method and apparatus claims for the regulation of the line current so as to regulate the induced currents simultaneously, unlimited in their terms as to the style of apparatus or current used, and also has claims for the method of and apparatus for generating and transmitting electrical currents and utilizing them to produce induced currents, with no limitation other than the expression "maintained and practically uniform," applied to the style of line-inducing current employed.

The interpretation of Patent C is much less involved. Its two claims enumerate specifically, in combination with the line, the generating apparatus, and the transformers and local circuits at the receiving stations, step-up transformers for utilizing the induced currents at the receiving stations and for transforming them to high-tension currents. There can be found for considerable doubt as to whether or not invention can be predicated upon the use of an additional transformer for stepping-up a current after it has been stepped-down from the line current, when the use of a transformer for producing a current of different potential is known. But given its face value, this patent covers the use of a step-up transformer in a local circuit employing currents induced from a line-circuit current by a step-down transformer.

We next come to the consideration of the bearing of these patents upon the electrical industries of the present time. Upon telephony, I suppose they have little bearing. I believe that telephone apparatus is not used to any extent in the system shown in them. If it is, of course apparatus such as that shown in the patents would be covered by the claims thereof and would infringe the same.

Upon electrical lighting by means of alternating currents and transformers at receiving stations, I presume these patents have the greatest bearing. So far as I am aware, the electric lighting done in this way is by means of one alternating currents, that is to say, current with an alternately reversing potential, and not by means of either undulatory or interrupted currents, such as those developed by the apparatus of these patents.

So if claims 5 and 7 of Patent A are limited to the apparatus of the patent, I apprehend that this patent is not infringed by the manufacture, sale or use of alternating-current apparatus. But if its claims 5 and 7 are given a construction as broad as their terms, every alternating-current plant in the United States infringes both of them, and perhaps every factory in the country would be held to be a contributory infringer of claim 5. Similarly, if the claims of Patent B be limited to the apparatus of that patent, alternating-current apparatus does not infringe it. But if they are construed as broadly as their terms read, claims 6 and 9 are likewise infringed by every alternating-current plant in the country, and perhaps claim 9 by every factory therein, on the ground of contributory infringement, for I suppose that every alternating-current system has its line current regulated so as to simultaneously regulate the induced current at the stations. Furthermore, if the expression "maintained and practically uniform" of Patent B be construed so as to include alternating currents, the same plants likewise infringe claims 1, 3 and 5 of that patent.

If step-up transformers are used in the local circuits of such system, both claims of Patent C are infringed by the persons responsible for such use. I wish to repeat here, however, that I express no opinion as to whether or not these patents will be declared valid and construed in this liberal way. I am merely suggesting what would be the result if they were so treated.

Finally, as to the bearing of the patents, or their alleged bearing, upon the Tesla system of generation and transmission of energy. My understanding of the Tesla system is that it involves, essentially, the production of a rotary magnetic field by the development in independent circuits of alternating currents, differing in phase from one another, and does not in itself involve the use of transformers. In such case, I am unable to see that it and the Hunter patents have any relation or connection or bearing upon one another whatsoever.

If there should be employed in connection with the Tesla system transformers for use in any one of its independent circuits, as I understand is frequently if not even generally done, of course such circuit would be subject to the claims of these Hunter patents in the manner I have hereinbefore indicated with reference to electric-lighting distribution circuits, because the expression "translating device" used in these claims includes motor field magnets as well as electric lamps. But this infringement of the Hunter patents by the users of the Tesla system evidently does not result from the employment of the Tesla system per se, but is merely incidental thereto, just as a similar infringement of the patents might result from the use of transformers in connection with any other system.

From these observations, it appears to me that there is room for a clash between the owners of the Hunter patents and the makers, sellers and users of electric-lighting and other systems employing line-inducing currents and receiving-station transformers, local circuits and translating devices; but that there is no such relationship between the Hunter patents and the Tesla system per se as to subordinate persons making, using or selling the devices essential simply to the principles of the Tesla system, or employing the method involved in the use of such principles alone, to the claims of the Hunter patent.

Electric Railways in Germany.

The Elektrotechnische Zeitschrift published at the beginning of the year full statistics of the electric railways in Germany, brought down to September 1, 1897, showing the rapid growth of electric traction in that country. At the close of 1891 but three towns had electric traction in use, while in 1897 the number had increased to 56, and in addition 7 had definitely decided to adopt electricity for tramway service. Of these 34 it was expected that eight would be in operation before the end of 1897, so that the total number of cities using electric traction at the beginning of the present year is 64. The existing roads have more than 600 miles of track, of which about one-half is double, and, with the exception of 11 miles of underground road in Berlin and less than 25 miles of storage-battery system, this is all overhead trolley.

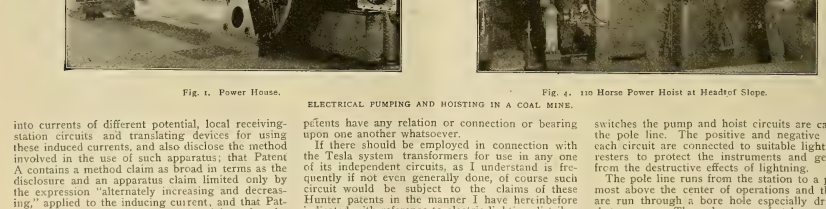

Fig. 1. Power House. Fig. 4. 110 Horse Power Hoist at Headtof Slope.

ELECTRICAL PUMPING AND HOISTING IN A COAL MINE.

Electrical Pumping and Hoisting in a Coal Mine.

Four miles north of Wilkesbarre, Pa., in the mines of the Lehigh Valley Coal company, an interesting electrical installation has been in operation during the last year. The main workings of the mines are under the Susquehanna River Flats, eastward from the shaft toward that river from the Wyoming Hills—the western outcrop of the anthracite coal belt. As the workings were extended the problem of handling the constantly increasing volume of water became daily more difficult and the haulage of coal by mules more expensive. A steam plant on the flats was impracticable on account of their submersion, and after careful investigation the company decided to use electricity for the operation of the mine pump, and an electric cable hoist for the haulage of the coal over an extension of the main gangway.

The power house (Fig. 1) is placed near the head of the main hoisting slant and contains the main hoisting engines, the generator and its driving engine. Steam is supplied from a battery of boilers set in another house about 200 feet away. The dynamo is a General Electric slow-speed, 150-kilowatt, direct-current, six-pole machine, driven by a Ball automatic tandem compound non-condensing engine. The speed of the engine is 200 revolutions per minute, that of the generator 400 revolutions per minute. The generator is compound wound for 500 volts at no load and 550 volts at full load. An iron switchboard is placed against the wall of the engine room, and current passes from the generator to the switchboard through heavily insulated copper cables suspended on porcelain insulators in a conduit under the floor. The conduit is provided with a removable cover, allowing ready access to the cables. The board is provided with two double-pole feeder switches for the pump and hoist circuits in addition to the main double-pole station switch. The pump circuit is protected by fuses, the hoist circuit by an automatic circuit breaker. From the two feeder switches the pump and hoist circuits are carried to the pole line. The positive and negative sides of each circuit are connected to suitable lightning arresters to protect the instruments and generators from the destructive effects of lightning.

The pole line runs from the station to a point almost above the center of operations and the wires are run through a bore hole especially drilled for that purpose. The poles are 30 feet long, and each carries one four-pin crossarm with iron braces, wooden pins and glass insulators.

The positive feeders for the pump and hoist circuits consist of two separate No. 0000 B. & S. wires, and two No. 0000 B. & S. provide a common return. At about 5,000 feet from the power house two bore holes, each 350 feet deep, are driven from the surface of the flats. One is provided with a six-inch iron pipe as a casing for the wires, the other with a 12-inch casing for the pump discharge. The six-inch pipe rises about 18 feet above the surface of the ground; the opening is thus protected against any great rise of water during freshets. A small cable house is supported on this pipe, into which the line wires pass and make connection with the cable in the bore hole. The two positive feeders are connected to two separate cables, and the common return wires to one large negative cable. Each cable is heavily insulated with rubber and jute braid and then leaded and armored with iron wire protected from corrosive and electrolytic action by tarred jute. The cables are supported from the top of the standpipe, as shown in Fig. 2. The method of suspension of the cables is unique. Six cast-iron plates 1½ inches thick and 18 inches square are drilled with three two-inch holes close together near the center of the plate. The six plates are placed one above the other on top of the stand-pipe, and the cables pass through the holes in all of the plates. The six plates are then in three sets, each one in a set forming a clamp tightened by several small bolts. As one cable passes through the bottom clamping set the iron-armored wires are spread out and tightly clamped between the two plates. Another passes through the hole in the first set and is clamped between the plates of the second set, the third armored cable being held between the third set. Each cable is, therefore, supported by its own armor and a separate clamp. These additional lightning arresters protect the cable and line wires in the cable tower.

At the bottom of the hole the cables are connected by single-pole switches to the circuits operating the hoist and pump, 600 feet distant. These underground wires are double rubber-covered and are supported on glass insulators fastened to props along the ribs. A wooden switchboard carrying fuse boxes, main switch and starting rheostat for the pump is erected in the pump chamber.

The motor for this pump (Fig 3) is mounted on a cast-iron bed plate and is geared by a double-reduction gearing to the crank-shaft operating the plungers. The motor is a General Electric shunt-wound machine, with a capacity of 85 horse power continuously at a speed of 600 revolutions per minute. The pump is a duplex, double-acting, pot-valve pump, manufactured by the Jeansville Iron Works, with outside-packed and connecting plungers, 10 inches in diameter by 18 in stroke. The pump capacity at 25 revolutions is 600 gallons per minute, under a head of 360 feet. As with all pumps operated with shunt-wound motors, the speed of the gearing is approximately constant—a great advantage where the pump receives little attention and where the pump capacity is limited. Should the pump happen to run on air, there would be no racing, as in the case of air and steam pumps, and the amount of energy consumed is only that required to overcome the mechanical friction of the rotating parts. The suction pipe drains from a large sump near the pump chamber and the water passes up through the 12-inch bore hole to the surface, where a check valve prevents the water returning during any freshets when the pump is not in operation. A small four-inch by six-inch triplex plunger pump, geared to a five horse power multipolar slow-speed motor, pumps water up the small slope to the large electric pump.

The hoist (Fig. 4) is placed at the head of a small slope extending east from the parting at the foot of

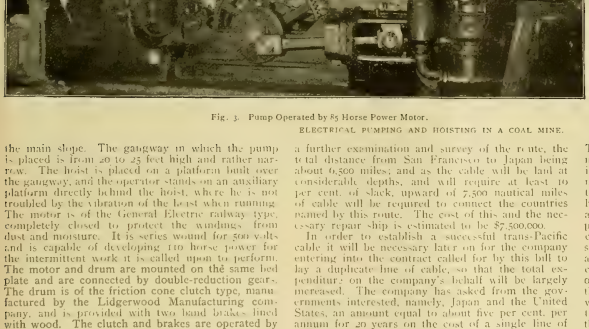

Fig. 3. Pump Operated by 85 Horse Power Motor.

ELECTRICAL PUMPING AND HOISTING IN A COAL MINE.

the main slope. The gangway in which the pump is placed is from 20 to 25 feet high and rather narrow. The hoist is placed on a platform built over the gangway, and the operator stands on an auxiliary platform directly behind the hoist, where he is not troubled by the vibration of the hoist when running. The motor is of the General Electric railway type, completely closed to protect the windings from dust and moisture. It is series wound for 500 volts and is capable of developing 110 horse power for the intermittent work it is called upon to perform. The motor and drum are mounted on the same bed plate and are connected by double-reduction gear. The drum is of the friction cone clutch type, manufactured by the Lidgerwood Manufacturing company, and is provided with two band brakes lined with wood. The clutch and brakes are operated by three levers and quadrants, while the motor is operated by a rheostatic controller to the left of the levers. The controller is provided with a magnetic blow-out. The hoist drum is 48 inches in diameter and 36 inches face and holds about 1,400 feet of one-inch wire rope. Under full load the rope strain on the hoist, at an average speed of 500 feet per minute, is rated at 5,000 pounds. The hoist is operated under the three-rope system; the empty trips are lowered by gravity and overhaul the rope, while the loaded trips are hauled up out of levels situated at intervals along the slop. The lowest level is about 1,200 feet from the hoist. The slope pitches on an average about 5°, with a maximum of 8° at the approach to the knuckle, above which the empty and loaded trips pass on a parting directly under the hoist. The usual load up the slope is four loaded cars per trip at an average speed of 500 feet per minute. Each car weighs about 1½ tons, loaded, and in case of necessity the hoist is capable of hauling six cars per trip.

The installation of this plant was effected by the General Electric company, and since it was started it has operated continuously with satisfactory results.

Pacific Cable Project.

[Special correspondence of the Western Electrician.]

Washington, D. C., March 14—The bill relative to telegraphic communications between the United States, the Hawaiian Islands, Japan and China, which has been before the committee of the whole house, has been amended by the substitution of House bill 6561, and for making the change the committee gives the following reasons:

The committee is strongly impressed with the importance of establishing, at the earliest possible date, suitable cable connections between the United States and the countries named, also incidentally with Europe, via Siberia and Russia.

The Hawaiian Islands, from their geographical position, look upon the United States as their natural commercial ally, and we have a great and growing interest in the commerce of these islands, as well as with Japan and China. Trade between the United States and these countries is undeveloped, and cheap and effective cable communication is essential.

Within the last few years the United States government has been at great expense in the maintaining of warships for the purposes of communication between California and the Hawaiian Islands, owing to the lack of means of cable communication, and so far as Japan, China and other portions of the Asiatic continent are concerned, the present rates charged for messages between the United States and those countries are so high as to be practically prohibitory except where matters of the highest importance are involved.

The proposed cable will start from San Francisco and proceed to the Hawaiian Islands, a distance of 2,097 miles, and thence to Japan and such other islands in the Pacific as shall be determined after a further examination and survey of the route, the total distance from San Francisco to Japan being about 6,500 miles, and as the cable will be laid at considerable depths, and will require at least 10 per cent. of slack, upward of 7,500 nautical miles of cable will be required to connect the countries named by this route. The cost of this and the necessary repair ship is estimated to be $7,500,000.

In order to establish a successful trans-Pacific cable it will be necessary later on for the company entering into the contract called for by this bill to lay a duplicate line of cable, so that the total expenditure on the company's behalf will be largely increased. The company has asked from the governments interested, namely, Japan and the United States, an amount equal to about five per cent. per annum for 20 years on the cost of a single line of cable. This request is based on the theory, well recognized by cable experts, that the life of an ocean cable is ordinarily about 20 years, and that all well-regulated cable companies must accumulate from their net earnings each year an amount sufficient at the end of 20 years to renew its cables. The amount per annum, therefore, which this cable company asked, viz., $200,000 from the government of Japan and $175,000 from this government, was simply sufficient to provide a renewal fund for one line of its proposed cable at the end of 20 years. The committee has felt that the amount asked from this government was somewhat larger than should be granted, and has therefore reduced the amount to $100,000 per year.

The risks of cable ownership are very considerable. The item for repairs and renewals is an uncertain one and at times a very costly one, the committee having satisfactory proof that the repairs to an Atlantic cable have cost as much as $500,000 at a time for a single repair. This is one of the reasons that the committee has rejected against governmental ownership of any trans-Pacific cable.

Under the contract proposed, the Pacific Cable company of New York will transmit free of cost for all time the official messages of the United States government, giving to those messages the right of way. These measures are estimated to amount to about $25,000 per annum at the present time, and this is likely to be increased from year to year.

The rate for commercial messages will be $1.25 per word to Japan and China and 35 cents per word to Honolulu, and press rates to be not more than one-fourth the rate that shall be charged for ordinary private messages.

It is pointed out that former offers have been based upon a yearly subsidy of $250,000 in one case, and in the other $150,000 annually, merely to lay a cable to Honolulu. Another point is the fact that no payment is asked from the United States government until the cable is laid and in efficient working order.

It undertaken this will be the longest cable in the world. It will be laid in an unknown ocean, and soundings show that at one point it will be in 3,185 fathoms of water. If the proposed contract is accepted the cable company will assume all risks of construction and the continual working of the cable. If it should break down the assistance rendered by the government would cease during the interruption.

The Pacific Cable company of New York, with which it is proposed that the contract in question should be made, is organized under the laws of the state of New York, with a capital of $10,000,000. The company proposes to build its cable by sales of its stock, and does not propose to issue bonds,

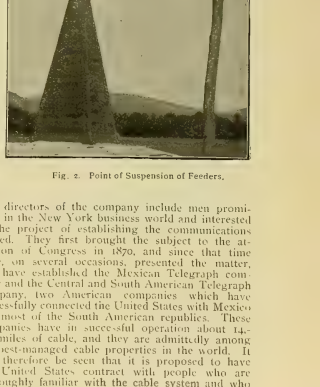

Fig. 2. Point of Suspension of Feeders.

The directors of the company include men prominent in the New York business world and interested in the project of establishing the communications named. They first brought the subject to the attention of Congress in 1870, and since that time have, on several occasions, presented the matter, and have established the Mexican Telegraph company and the Central and South American Telegraph company, two American companies which have success-fully connected the United States with Mexico and most of the South American republics. These companies have in succe-sful operation about 14,000 miles of cable, and they are admittedly among the best-managed cable properties in the world. It will therefore be seen that it is proposed to have the United States contract with people who are thoroughly familiar with the cable system and who have successfully laid and maintained an extensive system of cables.

A. F. T.

Representative Corliss of Michigan on March 12th completed the minority report of the House committee on interstate and foreign commerce against the bill reported by that committee for the establishment of a Pacific cable. The original bill provides for the subsidy of the Pacific Cable company at the rate of $100,000 for 20 years, and provides for the completion of the cable to Honolulu by 1900 and to Japan and China by 1901.

The minority report indorses the proposition for a cable, but objects to the bill of the majority, because it grants an exclusive monopoly and subsidy of $2,000,000, and holds that all franchises should be open to competition; also, that another American corporation is ready to enter into a contract to construct the cable.

It is believed that for the public good the president should be clothed with power to secure the co-operation of Japan for the construction and maintenance of this important public work.

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO.

TELEPHONE, MAIN 1746.

EASTERN OFFICE: 108 TIMES BUILDING, NEW YORK.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome, and communications, views, new ideas, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own.* THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

HIGH WATER MARK

CIRCULATION, 20,000.

State of Illinois, County of Cook—ss.:

Thomas Jansen, being duly sworn, deposes and says that he is a resident of the city of Chicago, in the county of Cook and state of Illinois, and that he is the foreman of the printing department of the Electrician Publishing company, the publishers of the Western Electrician; that he was present at and superintended the printing of No. 24 of Vol. 20 of the Western Electrician, issued on June 12, 1897, and that there were printed by actual count 20,000 complete copies of said Western Electrician of the volume and number above specified. And further this affiant sayeth not.

THOMAS JANSEN.

Subscribed and sworn to before me this 27th day of July, 1897. Chicago, July 27, 1897. IRA B. JONES, Notary Public.

Illustrated Electrical Patent Record 178

Whatever objection may be urged against the plan of the Chicago City Railway company to equip the Wabash avenue and State street lines in the down-town district electrically, it may be said that it is not the intention of the company to consider the third-rail system, even upon the suggestion of such an eminent authority as the Chicago Times-Herald. That journal says that "the third-rail plan is more costly than the overhead trolley, but that is the sole objection which can be urged against it." Our contemporary no doubt had the conduit electric system in mind when it mentioned the "tairdrail plan." At any rate, it is to be hoped that it did not seriously consider the advisability of using the third-rail system on surface lines in crowded city streets.

Municipal ownership forms an important and prominent feature of the local elections at Des Moines and Milwaukee this year, and it also enters the contests at Petoskey, Mich., and other points. The objections urged in Milwaukee and Des Moines are the same that have stood in the way of a municipal plant for several years. Mayor MacVicar seems to be the leading advocate of the scheme in Des Moines, and his personal following will doubtless advance the interests of the project. In Milwaukee the intense feeling that has been displayed against the established corporation has not abated, and it may be said that the success of a proposition to build a city plant in that town will be largely due to the opposition to the men engaged in the local company. In Petoskey the aldermen seem to be wholly at sea.

General Greely made a strong case in pleading for a small appropriation from Congress to be used in laying cables and providing means of electrical communication with the fortifications and other defenses along the coast. In crises such as that now existing in the relations of the United States and Spain it comes as a painful shock to realize that important fortifications in the harbors of Boston, San Francisco and other cities are totally without means of instantaneous communication with the mainland and the other forts. In case the defenses are called into service the need of intelligent and prompt co-operation is obvious; and it seems to be a short-sighted policy to expend millions on elaborate enginery of destruction and withhold the few thousands that would add so greatly to the effectiveness of operating the plant. It is true that the cables can be quickly laid; and it is gratifying to learn that the work is to be undertaken immediately, the cost to be defrayed from the special national defense fund of $50,000,000.

In announcing that Hiram W. Sibley of Rochester has bought from Stephen Vail of New York and presented to Cornell University for the Museum of the Sibley College of Mechanical Engineering the original telegraph receiver on which was taken the first telegraph message over Morse's line from Baltimore to Washington, the Ithaca correspondent of the New York Tribune notes that Cornell is an appropriate repository for this gift, inasmuch as Ezra Cornell put up that first line of telegraph wire, and subsequently made out of the other lines the fortune with which he endowed the university. It might have been added that Hiram Sibley, the father of the gentleman making the gift, made the foundation of his large fortune, too, out of the early extension of the electric telegraph. Hiram Sibley was one of the incorporators of the Western Union company, and was the man who originated, and very largely carried through, the undertaking of the overland telegraph connecting California and the East in 1857-1861. He was prominently identified, too, with the vast project of a line of telegraph to connect the United States with Europe by way of Behring Strait and Siberia, which was abandoned on the successful working of the Atlantic cable. Mr. Sibley was intimately associated with Ezra Cornell and largely endowed the college of Cornell University which bears his name. He was a man of great force of character. He lived to an advanced age, dying in Rochester about 10 years ago.

Electric carriages have attracted the attention of German officials, and the favor with which they are regarded promises well for their development and general adoption in social life in the larger cities. In Berlin several of these carriages are in daily use, and, according to the Elektrotechnische Zeitschrift, they are giving satisfaction. Carriages of this class are built by one of the leading cycle companies of Germany and they are fitted with bicycle wheels and pneumatic tires, which can be inflated to a pressure of 120 pounds, while the bodies are supported on steel tubular frames. The wheels have ball bearings, and steering is effected by means of a lever connected with the front pair of wheels. Each carriage is equipped with a motor suspended from a steel frame lying parallel with the rear axle, the latter passing through the hollow armature shaft, and being driven by differential gearing from a toothed wheel arranged on that shaft. The battery consists of 44 cells in four boxes, the total weight being 800 pounds. It can be charged at a pressure of either 65 or 110 volts, and the connections allow of four different speeds being attained, three by altering the disposition of the battery and one by weakening the motor field. The carriage is provided with a watt-hour meter, which indicates the condition of the battery, and the total weight complete is 1,600 pounds. It is possible to attain a speed of 12 miles an hour, and one charge is sufficient for a distance of 40 miles.

In London very little has been said about the electric carriages or cabs that were put in service several months ago. In Paris there was considerable activity in this industry for awhile, but the French seem to prefer the dirty, foul-smelling oil-engines to the electrically propelled motors. However, it is hardly becoming in Americans, and Chicagoans particularly, to criticize others for neglecting to support this important branch of the business.

No class of inventors in the United States is more interested in the Patent Office than the electrical contingent, and no class of investigators has contributed more to the success of this important branch of the government service than those occupied with the solution of electrical problems. The prominence of the electrical fraternity in Patent Office work and the remarkable expansion of the industry as indicated by the official records are subjects of special consideration in the annual report of the commissioner of patents for the calendar year 1897, which was submitted to Congress on March 14th. Some interesting statistics are presented which may be fittingly reproduced here:

In the electric-light and power industry, as reported in 1880, there were but three establishments in the United States, employing 229 persons and producing an output valued at $458,400. At the close of 1897 there were in the United States 2,124 central stations supplying electricity for light and power and 7,475 isolated plants, a total of 9,599 establishments. The capital invested in these central stations is stated to have been $258,956,256, and the capital invested in the isolated plants, though not stated, was probably not below $200,000,000. A conservative statement of the number of persons employed at that time in this industry would not be under 45,000.

The use of electricity for power purposes has found its most notable development in the electric railway. The first electric street railway in the United States was put in operation little more than 10 years ago. In 1880, of the 2,500 road-miles of street railway in the United States nearly all used animal power. The total mileage of electric railways in the United States up to October of 1897 was 13,765 miles, out of a total mileage of 15,718, of which but 947 miles were horse-car lines. The total capital invested was $846,131,691.

The telephone in 1880 was just beginning to be commercially known. At the close of 1896 there were in the United States 967 telephone exchanges and 832 branch offices, using 536,845 miles of wire and employing 14,425 persons. The total amount stated to be invested in telephone property in 1895 was $77,500,000.

The volume of business transacted by the Patent Office during the year and the proportion of electrical cases considered compares favorably with the reports of former years, especially when the conditions that obtained during the last year are remembered.

It may not be amiss to call attention to another feature of the report which has direct bearing upon the character of the service of this branch of the government. The Patent Office is self-sustaining; more than that, it provides a surplus each year, the amount being increased last year by $252,798. The total balance of the Patent Office in the treasury of the United States on January 1st was $1,971,438. And yet Congress refuses to authorize expenditures that will facilitate the work and provide suitable accommodations for the Patent Office.

International Convention at Laredo, Texas.

[Special correspondence of the Western Electrician.]

Laredo, Texas, March 14.—The joint meeting of the Texas Gas and Electric Light association and of the Texas Street Railway association in this city on March 9th, 10th and 11th was favored with the fine weather customary in this section of the country. The associations, both as organizations and as individuals, met with the hearty reception characteristic of the people of the Rio Grande valley, the citizens of Laredo and of Nuevo Laredo, as well as of the states of the Republic of Mexico, vying with each other in their efforts to make the visitors welcome. The following-named delegates were present:

W. H. Weiss, San Antonio,	R. S. Wakefield, San Antonio,
B. F. Bonner, Houston,	E. Dysterod, Monterey, Mexico,
G. H. Cushman, San Antonio,	B. M. Hammond, San Antonio,
J. E. Johnson, Austin,	H. L. Monroe, Dallas,
T. H. Stewart, Waco,	F. Fries, San Antonio,
Max Levy, Galveston,	W. E. Hamilton, Shreveport, La
Frank E. Scoville, Austin,	W. M. Brooke, Lardeo, Texas,
V. E. Raggio, St. Louis,	A. W. Dutton, St. Louis,
J. R. Cox, Galveston,	J. H. Fitzgerald, Houston,
L. T. Fuller, Calvert,	T. D. Miller, Dallas,
Carl F. Drake, Austin,	E. E. Taylor,
C. F. Yeager, Laredo,	E. L. Wells, Jr.,
W. E. Holmes, Austin,	H. W. Adams,
J. F. Strickland, Waxahachie,	J. D Gibb.

Honorary Members.

Antonio de la Fuente, Monclova, Mexico.
Jose M. Fejada, Monclova, Mexico.
Martinez Negrete, Sr., Guadalajara, Mexico.
Martinez Negrete, Jr., Guadalajara, Mexico.

Prominent Mexican Officials.

L. de la M. Gonzales, Nuevo Laredo, Mexico.
Carlos A. Passament, attorney and president of the Supreme Court of Justice of the state of Tamalipas, Mexico, Victoria, Mexico
Rosemo Valdez, judge of Nuevo Laredo, Mexico.

INTERNATIONAL CONVENTION AT LAREDO, TEXAS

On Wednesday evening the Mexican National Band of the First Regiment of Artillery, the pride of the president of Mexico, arrived from the City of Mexico, and from that time until the visitors dispersed entertained the guests of the occasion with its superb music. This band, consisting of 45 pieces, is the Mexican band that visited the World's Fair at Chicago, and has since been selected to attend the Paris exhibition in 1900. It was sent to Laredo on this occasion, a distance of 865 miles from the City of Mexico, as a special compliment to the associations, by President Diaz. In justice to the associations, it might be said that an immense silver plate, elegantly engraved, will convey the appreciation of the delegates of such a magnanimous act to the beloved president of our sister republic.

The appreciation by Laredo of the honor conferred on her by selecting this city as the meeting place was apparent everywhere and at all times, the decorations and illuminations being particularly admired and the subject of frequent favorable comment by the lighting fraternity.

The exhibits made by many supply men in attendance were tastefully arranged and proved to be an attractive feature. The programme of the meetings as already published was followed closely. At the close of the meeting the delegates were taken on an excursion to Monterey, Mexico, where they were entertained on Saturday and Sunday.

Nearly all of the papers presented during the meeting were subjects of wide and interesting discussion. The lecture and experiments by Mr. Dysterod on X-rays and high-frequency currents were not only delightfully entertaining to the large attendance, but were highly interesting and instructive to the experts of the lighting business, and the delegates pronounced the experiments the best they had ever seen. Another interesting feature was the address by Carl F. Drake of Austin in response to the welcoming address by the mayor of Laredo. It abounded with sentiment and eloquence, and his reference to the friendly relations between the sister republics evoked prolonged applause from the Mexican delegates.

Upon the conclusion of the programme both organizations adjourned sine die, and immediately there was organized the Southwestern Gas, Electric and Street Railway association, to embrace particularly the territory of Texas, the Republic of Mexico, Louisiana, Indian Territory, Oklahoma, Arkansas and New Mexico. The following-named officers were elected for the ensuing year:

President, Carl F. Drake of Austin, Texas.

First vice-president, J. H. Fitzgerald of Houston, Texas (to represent the gas interests).

Second vice-president, E. Dysterod of Monterey, Mexico (to represent the interests of the electric-lighting fraternity).

Third vice-president, W. H. Weiss of San Antonio (to represent the interests of the street-railway people).

Treasurer, F. Fries of San Antonio.

A photograph of a number of the delegates in attendance is herewith reproduced. Fifteen new members were admitted during the meeting. Thirty-six delegates represented gas and electric-lighting interests and the remainder representd street-railway interests.

The addresses to the public were translated and delivered extemporaneously by Louis de Antin, superintendent of public schools of Laredo, Texas, the English addresses being translated into Spanish, and vice versa.

T. D. M.

Commercial Cable Company.

The annual meeting of the Commercial Cable company was held last week. The revenue from the operations of the cables, after deducting all expenses, amounted to $1,209,155, an increase of $70,502 over the previous year. The net revenue from the land lines (Postal Telegraph company) was $645,185. The net revenue from the combined systems was $1,845,341. Out of this have been met the interest on the first-mortgage bonds and debenture stock, dividends of seven per cent. on the stock and bonus of one per cent. on the capital stock—a total of $1,440,000—leaving the balance of net revenue for the year $405,341.12. The further sum of $250,000 will be set aside and invested in high-class securities as an addition to the reserve fund, which will then stand at $2,668,329. There have been added to the land-line system during the year 933 miles of new pole line and [illegible] miles of wire. The directors elected for the ensuing year were John W. Mackay, James Gordon Bennett, Gardiner G. Howland, Colonel William Jay, George G. Ward, Sir William C. Van Horne, E. C. Platt, the Rt. Hon. Lord Strathcona and Mount Royal, Charles R. Hosmer, Thomas Skinner, Clarence H. Mackay, Albert B. Chandler and Dumont Clarke. At the meeting of the directors, which followed, these officers were named: President J. W. Mackay; vice-president and general manager, G. G. Ward; vice-presidents, C. R. Hosmer, A. B. Chandler and C. H. Mackay; treasurer, E. C. Platt; secretary, Albert Beck; assistant secretary, J. O. Stevens.

National Electric Light Association.

Representatives of the electric-lighting and allied interests in and about Chicago are actively engaged in preparations for the forthcoming meeting of the National Electric Light association on June 7th, 8th and 9th. An unusually large attendance is expected, as this is the first time in several years that Chicago has been selected as the place of meeting. Central-station men throughout the West and Northwest who have been unable to attend the eastern meetings are showing considerable interest in this year's gathering, and there will undoubtedly be many new faces at this convention. Another source from which additional attendance will be insured is the street-railway interests of the state. Illinois has a young and energetic state association of street-railway companies, and this organization has named the week in which the National Electric Light association will meet in Chicago for its annual convention, as the railway men realize that there is much in common between the two interests.

Many plans and suggestion were considered by the gentleman invited to confer with President Insull on March 10th upon the arrangements for the entertainment of the visitors during the convention. Formal announcement was made of the action of the association in naming June 7th, 8th and 9th as the time for holding the meeting and the selection of the Auditorium Annex, Chicago, as the headquarters of the association. The banqueting hall which has been secured for the sessions is one of the finest meeting rooms in the country. Space will be furnished for exhibits in the hotel parlors and basement. There will be no general exhibit, the manufacturing and central-station interests agreeing upon that point. President Insull announced that the plant of the Chicago Edison company would be open to inspection at all times during the meeting and that every facility would be afforded members to examine the practical workings of the system. He said that the company would also afford facilities for manufacturers to display their apparatus and specialties in actual operation in the Edison stations. In other words, the Chicago Edison company will keep open house for the association during the convention.

Assurances were received from the street-railway companies and the elevated as well that they would co-operate with the lighting interests in giving the visitors an idea of the advancement that has been made in the electrical development of Chicago since the last meeting in this city. It was also suggested that a visit to the drainage canal would be interesting, especially to the eastern visitors.

It is proposed to hold morning and evening sessions, devoting the afternoons to entertainment and sight seeing. This plan has been tried at the Edison conventions and has proved satisfactory and popular. No definite action was taken on any of the plans suggested, as it was deemed expedient to await the result of President Insull's conference with the eastern representatives. Another meeting of the Chicago committee will be held on Thursday, March 24th, at which time the views of the eastern members will be presented and definite action taken.

An independent telephone exchange is in operation in Pittsfield, Ill., with 100 local subscribers and connections with nearly all the towns of Pike and adjoining counties.

DEVELOPMENT OF THE TELEPHONE FIELD.

Praise for the Western Electrician's Independent Telephone Number.

Additional proof of the favor with which the Western Electrician's Independent Telephone Number was received is presented in the words of praise that are received daily on this subject, some of which are presented herewith. Much interest is also manifested in this journal's new department on the "Development of the Telephone Field," and the hearty co-operation and the encouragement received from the independent manufacturing and operating companies is extremely gratifying.

Elkhart Telephone Company, Elkhart, Ind.: We are glad to see you espouse the good cause in such an earnest manner.

Hudson Telephone Company, Jersey City, N. J.: We are pleased to note the unlimited space you give to the subject of telephones.

Inter-state Telephone Company, Edgemont, S. D.: We are much pleased with your articles on the independent telephone work.

Hammacher, Schlemmer & Co., New York: Your Independent Telephone Number was an excellent one and has been a source of much information to our advertising man.

H. C. Underwood Manufacturing Company, Wabash, Ind.: We are very much pleased with the advertisement in your issue of the Independent Telephone Number, and we consider the issue very attractive.

Taber & Mayer, Boston: The Independent Telephone Number is excellent; it cannot fail to bear rich fruit and aid in keeping the Western Electrician in the front rank of electrical journals, where it belongs.

Warren and Niles Telephone Company, Warren, O.: We think your Independent Telephone Number was very comprehensive and satisfactory, especially to anyone interested in the opposition movement.

Ericsson Telephone Company, New York: We found the Independent Telephone Number very interesting, and we believe it should be productive of good results. We consider that it shows enterprise on your part.

Non-Polarizing Dry Battery Company, New York: We were very much pleased with your issue of the Independent Telephone Number. It looked very neat indeed, and we noted that you had a nice class of advertisers.

Reading Electrical Manufacturing Company, Reading, Pa.: As to your telephone issue we can only say that we are getting inquiries and orders by every mail. We thank you for the care in our "ad" and wish you a prosperous year.

James D. Randall, Memphis, Tenn.: I was delighted with the telephone edition of your paper, published February 26th. The "ads" were artistically set up and illustrated and the reading matter was just what we want. I hope that you will be able to give us more like this number.

Phoenix Electric Telephone Company, New York: The business brought us from the advertisement in your Independent Telephone Number doubled our anticipations, and we must say that never have we given an advertisement to any newspaper bringing us in results equal to those of this number.

Edison Manufacturing Company, New York: We consider the special telephone issue of the Western Electrician a most valuable contribution to telephone literature, and as we understand that it has been sent to every independent telephone exchange in the United States, it will undoubtedly be most carefully preserved for reference.

Mutual Telephone Company, Des Moines, Iowa: We were very much pleased with the Independent Telephone Number, and sincerely trust that you will find the field broad enough to continue, at least to a certain extent, the publication of news touching upon the work already done and being done by the independent telephone companies.

Hatch Storage Battery Company, Boston: Our opinion of the Independent Telephone Number, after a careful perusal of its contents, is that it cannot fail to be of the greatest assistance and benefit both to the telephone companies and the public. We have had several inquiries about our battery since our "ad" has appeared in your valuable paper.

Stromberg-Carlson Telephone Manufacturing Company, Chicago: We sincerely congratulate you upon your marked success in the Independent Telephone Number of February 26th and the space devoted to the "Development of the Telephone Field" in succeeding issues, and believe you should have the most hearty welcome and support of all interested in independent telephony.

James M. Thomas, President of the Independent Telephone Association of the United States of America, Chillicothe, Ohio.: I am greatly pleased with your special telephone number, and desire to congratulate you upon the broad plan which you adopted in editing it. This number is very encouraging to the independent telephone stockholders, and I hope your able journal will receive due return for the interest that you have taken in this movement. I thank you on behalf of the association.

Richland County Telephone Company, Richland Center, Wis.: We wish to thank you for the able support you have extended to the independent movement. In our estimation the Western Electrician should be in the hands of every independent company in the field. We wish you the success due you in your efforts to educate the people in this as well as other electrical subjects.

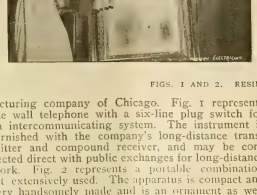
Michigan Pipe Company, Bay City, Mich.: We think that your Independent Telephone Number was very complete in every sense of the word. You gave in your news columns a full account of the independent telephone business and an account of the men who are engaged in it. In your advertising columns you gave excellent announcements of the manufacturers who are engaged in every line of production of materials and instruments used in telephone construction. The Independent Telephone Number could not be excelled.

Pennsylvania Electric Company, Marietta, Pa.: Your issue of February 26th, which was largely devoted to information regarding the independent telephone movement throughout the United States, will do much toward clearing away serious doubts and misgivings in the minds of a great many people as to the legitimacy of the business. The dissemination of this kind of literature is calculated to work more practically to the independent movement than anything that can be done just at this time. We congratulate you on your successful effort, and hope to see more of a similar kind.

Western Telephone Construction Company, Chicago: We wish to congratulate you on your Independent Telephone Number. It was certainly gotten up in a very handsome manner, and covered the telephone situation thoroughly. The Bell company has tried to belittle the importance of the independent companies, but your independent telephone issue fully demonstrates that the antagonists of this gigantic monopoly are sufficiently equipped to give the Bell company a fight that we feel sure they will appreciate as being one hard for them to overcome. It is evident after reading your journal carefully that the people are arrayed against the extortionate charges that have been imposed upon them, and we feel sure that you have helped the cause of reducing the telephone rates materially.

Residence Telephone Systems.

One of the most unique telephone systems especially adapted for residences is that put on the market by the Stromberg-Carlson Telephone Manufacturing company of Chicago. Fig. 1 represents the wall telephone with a six-line plug switch for an intercommunicating system. The instrument is furnished with the company's long-distance transmitter and compound receiver, and may be connected direct with public exchanges for long-distance work. Fig. 2 represents a portable combination set extensively used. The apparatus is compact and very handsomely made and is an ornament as well as an instrument of great convenience.



FIGS. 1 AND 2. RESIDENCE TELEPHONE SYSTEMS.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

Representatives of the Bell telephone companies from Iowa, Nebraska, Kansas and Missouri met recently at Omaha and discussed a schedule of rates on interstate business.

There is talk of an independent telephone company connecting with Delta, Ia.

The Woodbine Telephone company contemplates extending its lines to Harlan, Ia., with a line from Portsmouth to Panama.

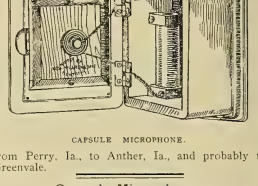
The scheme of the American Telephone and Telegraph company to get into La Crosse, Wis., without a franchise, by connecting with the Wisconsin Telephone company's system at the city limits has roused the ire of some of the aldermen and they declare that if the scheme is put through they will at once take steps to revoke the franchise of the Wisconsin Telephone company. They declare that the company said it was independent of the Wisconsin company, and this action, it is claimed, shows that the two companies are allied.

The Interstate Telephone company has been incorporated at La Crosse, Wis., with $100,000 capital stock. The incorporators are P. S. Elwell, George W. Bunge and Andrew Lees, three young attorneys of La Crosse. The company will be allied with the independent companies, and it is understood that the Winona Telephone company of Winona, Minn., is interested.

The Wisconsin Telephone company is arranging to extend a line from Chippewa Falls, Wis., to Stevens Point.

A long-distance telephone company will extend its wires to Morgan, Minn., this spring.

The Perry Telephone company will extend a line

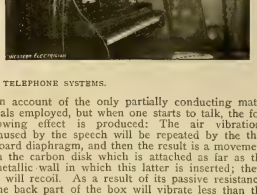


CAPSULE MICROPHONE.

from Perry, Ia., to Anther, Ia., and probably to Greenvale.

Capsule Microphone.

This transmitter has been fully tested in competition with other microphones and has given satisfactory results. The microphone is composed of two carbon disks inserted in the two halves of a small metallic box, each being insulated from the metal by means of a round of cardboard. The box is filled up to five-sixths of its height with granules of sifted carbon. One of the disks is fastened to the vibrating board, and a hole on each carbon serves to attach the wires for carrying the current; finally, the front of the disks which hold the carbon granules are slightly fluted to ensure contact with the carbon grains. When the receiver is removed from its hook, the current passes in small quantity.



on account of the only partially conducting materials employed, but when one starts to talk, the following effect is produced: The air vibrations caused by the speech will be repeated by the thin board diaphragm, and then the result is a movement in the carbon disk which is attached as far as the metallic wall in which this latter is inserted; there it will recoil. As a result of its passive resistance, the back part of the box will vibrate less than the front part; it will then cause a microscopic flattening of the microphone, a compression of the powder, and then an increase in the contact surfaces. The current will pass in larger quantity; it will go out on the line and attract the diaphragm of the receiver at the other end, so that the speech will be clearer, the vibration sharper and the compression more energetic. The simplicity, the small dimensions of this microphone, the number of its contacts and its power of transmission all combine to make it very popular, not only for private lines, but for long-distance service, and its good qualities have already been recognized. Two cells of battery must be used in every instance. An induction coil wound to 150 ohms gives the best results. Ness, McLaren & Bate manufacture this device. Their headquarters are at Montreal, Canada.

Mutual Telephone Company, Des Moines, Iowa.

During the recent meeting of independent telephone men at Des Moines, Ia., considerable interest was manifested in the exchange of the Mutual Telephone company of that city. The company organized about one year ago, and the construction of the plant was started March 1, 1897. Enough of the work was completed in time to open the exchange October 1st, with a list of 700 subscribers. This list now numbers nearly 1,200 subscribers. In the construction of the plant 12,740 feet of underground conduit having been built, 2,500 poles erected, 900 miles of wire strung and 22,000 feet of cable placed, all of which has been done under the direction and supervision of C. W. Bartlett, the manager of the company, whose portrait is herewith presented. An interior view of the Des Moines exchange is also shown, giving an idea of the operating room. The switchboard was built by the Connecticut Telephone company of Meriden, Conn.

As indicated by its name, the company is a mutual concern, and was organized on a somewhat different plan from most of the independent telephone corporations of the country. The company is authorized to construct toll lines from its principal exchange in Des Moines to such other towns and cities as may be deemed advisable. The company is also empowered to construct and maintain conduits under the streets and alleys of the city of Des Moines for the purpose of carrying telephone, telegraph, electric-light and other electrical wires.

The capital stock of the corporation is fixed at $50,000, divided into 2,000 shares of $25 each.

According to the articles of incorporation each shareholder of the corporation shall be entitled to the use of one complete connection on the general exchange switchboard, one telephone instrument and line connection from telephone instrument to the general exchange for each share of stock owned by the shareholder, the line connection to be within one mile of the general exchange. Shareholders desiring their line connections to extend outside of the one-mile limit shall pay an additional sum to cover actual cost of line construction outside of the mile limit, and any shareholder desiring to have his telephone moved from one part of the city to another may do so by paying for the actual cost of making the removal, including the cost of new line, if necessary, and under such regulations as the board of directors may provide.

The board of directors shall determine the amount that each of the shareholders shall pay to the corporation each quarter for service, which shall be the actual cost of maintaining, operating and keeping in repair the exchange, including all telephones, all line service and other necessary expenses. The amount shall be in all cases equal for business telephones and for residence telephones within a two-mile limit from the general exchange, but the charge shall not exceed $6 per quarter for business telephones and $4.50 per quarter for residence telephones within the two mile limit. The extra charge for telephones outside of the two-mile limit shall not exceed 75 cents per quarter per mile from the two-mile limit for each telephone in addition to the amounts fixed for telephones inside of the two mile limit.

The board of directors is also authorized to purchase additional telephones and to rent them and furnish exchange service to others than shareholders at such prices as shall from time to time be agreed upon.

Provision is made for turning the plant over to the city as follows: "This association may, in any charter to be granted by the city of Des Moines, agree that at the expiration of five years from the time the corporation commences business it will turn over to the city of Des Moines the entire plant, including central exchange, telephones, underground and overhead lines, at an appraised value, to be arrived at as follows: The city choosing one appraiser,

C. W. BARTLETT.

the company choosing one, and the two thus chosen to choose the third one, or on such other terms and conditions as may be agreed upon between the said city of Des Moines and this association."

The present officers of the company are J. W. Hill, president; D. F. Witter, vice-president; H. E. Teachout, secretary; A. C. Miller, treasurer; C. W. Bartlett, manager. The board of directors is composed of J. W. Hill, D. F. Witter, H. E. Teachout, A. C. Miller, Crom Bowen, J. D. Whisenand, G. B. Ellyson, M. McFarlin and Charles Mackenzie, and the executive committee, J. W. Hill, D. F. Witter, H. E. Teachout, J. D. Whisenand and M. McFarlin.

Mr. Bartlett, the superintendent of the company, is one of the most active anti-Bell men in the Northwest. He is an experienced business man and his

MUTUAL TELEPHONE COMPANY, DES MOINES, IOWA—SWITCHBOARD.

management of the Mutual company has produced marked effect upon the telephone interests throughout Iowa. Mr. Bartlett has taken a prominent part in the independent movement and is an active member of the Iowa association.

Commercial Telephony.

From the Telegraph Age.

In the present existing state of rivalry between the telephone and the telegraph, the telephone is steadily increasing in popularity, while the telegraph companies are barely holding their own and earn less and less profit each year.

It will be only a matter of time, a few years at most, before the telephone companies will control much of the commercial business of small towns which is now transacted through the medium of the telegraph.

Iowa Telephone Association.

The Iowa Telephone association, representing the independent telephone interests of the state, held its annual convention at Des Moines on March 8th. The association selected Des Moines as its permanent meeting place. The following-named companies were represented:

Spirit Lake Telephone company, by W. W. Pritchard.
Jefferson Telephone company, by C. G. Cockerell.
Perry Telephone company, by G. N. Bandy.
Boone Telephone company, by C. E. Wells and C. C. Deering.
Madrid Telephone company, by J. P. A. Anderson.
Marshall Telephone company, by W. G Bowe.
Oskaloosa Telephone company, by S. T. Slade.
Washington Telephone company, by C. D. Robinson.
Cedar Rapids Telephone company, by W. R. Durio.
Clearfield and Mt. Ayr Telephone company, by D. N. Smith.
Conway Telephone company, by G. A. Haynie.
Jefferson County Telephone company, by W. R. Hine
Waterloo and Cedar Falls Telephone company, by Dr. C. F. Bennett.
Knoxville Telephone company, by Mr. Bellamy.
Mutual Telephone company, by J. W. Hill and H. E. Teachout.
E. H. Martin Telephone company, by E. H. Martin.

An excellent programme had been prepared, including papers and practical talks by members. Following is a list of the papers and the gentlemen who presented them:

"Toll Rates," by M. Pritchard, Spirit Lake.
"Territorial Construction of Toll Lines and How to Build Them," by C. F. Bennett, Waterloo.
"Modern Switchboard and Appliances," by H. E. Teachout and C. W. Bartlett, Des Moines.
"Toll Line Accounts," by E. H. Martin, Webster City.
"Toll Line Signs," by G. N. Bandy, Perry.
"Exchange and Toll Rates," by C. G. Cockerell, Jefferson.
"Construction of Toll Lines and Material to Be Used," by C. E. Wells, Boone.
"Cables, Protection and Insulation," by C. W. Bartlett, Des Moines.
"Franchises and Use of Public Highways," by Major Mackenzie.

The membership of the association has been increased by one-third during the last year. There are now 34 operating companies in the association, and accessions to this number are expected. Communications were read from a number of companies expressing regret that they were not able to have representatives present, and saying they desired to join the association. One of these communications was from J. C. Hubinger, the Keokuk capitalist, who is interested in several lines.

C. E. Wells of Boone was elected president. He read a paper during the meeting upon the toll-line business, and this really formed the principal subject of consideration. Statistics were presented to show the marvelous growth of the independent toll lines in the state. Three years ago there was scarcely a mile of independent toll line in Iowa. Now there are 2,200 miles, and 1,000 miles of new toll lines are projected. This summer metallic circuits are projected which will connect with the important towns in the vicinity of Des Moines, with which there are now no independent connections.

The matter of covering territory with toll lines not already reached was discussed, and an agreement reached that each independent company should build into territory adjacent to its exchange, with the object of covering the state as thoroughly as possible, without paralleling lines and without unnecessary competition and expense.

It is understood that construction is to be begun at once of a metallic circuit line between Boone and Marshalltown, which will connect with Ames, Nevada, State Center and other towns. These will all be connected with Des Moines.

Arrangements have also been made for a metallic line from Des Moines to St. Joseph, Mo., connecting with the county seats. Through St. Joseph, Des Moines will be connected with St. Louis.

The present connection with Boone, Fort Dodge, Webster City, Perry, Jefferson and other points north and west will be made metallic the coming season. At present there are toll line connections with those places by grounded line circuits. The metallic circuit will be used for through business, and the grounded line for local business.

A line will also be built from Des Moines to Oskaloosa this summer. Cedar Rapids, Marion and Marshalltown will be connected this season.

A line will be built from Council Bluffs to Red Oak and other points in the southwest. A line will be built from Atlantic to connect with Creston.

Twenty-seven new exchanges are now in process of construction, or will be constructed this spring by members of the association and other independent companies. In the near future the association hopes to extend its toll-line service to connect with every town of importance in the state.

Steps will be taken to secure a better class of toll lines and uniformity in the construction of them. This will admit of a more satisfactory exchange of through business.

The association decided on a uniform sign for the independent companies. It is a blue and white enamel sign, 17 by 17 inches, made in the form of a Maltese cross, with the words upon it: "Local and Long-distance Telephone."

The association decided upon the Hawkeye Telephone Construction company, of which C. W. Bartlett of Des Moines is superintendent, as the concern which should be patronized by its members, the company agreeing to carry a full stock of supplies.

Canadian Bell Telephone Company.

The annual meeting of the Canadian Bell Telephone company was held in Montreal on February 23d. There were present at the meeting C. F. Sise, president; R. Mackay, F. X. St. Charles, G. A. Greene, P. R. Gault, Hugh Paton, C. R. Hosimer, R. Archer, R. W. Shepherd, Charles Cassils, T. D. Hood, F. G. Payne, R. P. McLea, C. A. Briggs, C. F. Paul, James Wilson, Herbert Wallace, George Sumner, H. A. Budden, M. S. Foley, E. Rawlings, John Crawford, J. A. Grenier, George H. Holt, D. Ross Ross, Charles Garth, F. B. McNamee, James Shearer, James Williamson.

The annual report was submitted. The net revenue for 1897 was $297,751.57, and after dividends have been deducted the company will carry forward $82,364.17 to its 1898 account. Nine hundred and eighty-three subscribers have been added during the year, the total number of sets of instruments now earning rental being 30,445. The company now owns and operates 349 exchanges and 261 agencies. Thirty-five miles of pole and 703 miles of wire have been added to the long-distance system in 1897; of these five pole-miles and 200 wire-miles are in the Ontario department, and 30 pole-miles and 494 wire-miles are in the eastern department. The long-distance lines now owned and operated by the company comprise 16,567 miles of wire on 6,095 miles of poles. Under the authority of the shareholders $66,500 bonds have been sold during the year, the premium thereon being 10 per cent. Continuing the policy adopted in former years, the directors have charged to contingent fund $150,000, that amount having been expended during the year on construction rendered necessary by the introduction of trolley and other wires, but which has not increased the earning power of the plant.

The following-named directors were elected: C. F. Sise, Robert Mackay, John E. Hudson, Robert Archer, William R. Driver, Hugh Paton, Charles Cassils, Thomas Sherwin.

Telephone Service at Washington.

A bill has been introduced in Congress for the erection and operation of a postal telephone system in Washington, to be under the control of the postmaster-general. The sum of $100,000 is asked for this purpose, which would be the means of connecting all the public buildings and government offices of the city.

The matter of charges for telephone service in the District has been brought to the attention of the Senate by means of a bill introduced by Senator Pettigrew, which provides that it shall be unlawful for any person or any telephone company doing business in the District to receive for the use of one telephone any more than the following rates: In hotels or other places of business, $50, and $36 for each telephone used in residences, within a radius of one mile from the telephone exchange, and for each additional mile a further charge to business places of $4 and for residences of $3; these prices to cover a service as efficient as any now rendered in the District. The bill further provides that any subscriber is entitled to telephone service for his servants and the members of his immediate family, but no other persons shall have the right to use without further charge any other telephone equipment, with the consent of the owner of same. Anyone charging in excess of these rates, or a refusal of any of these privileges, will be fined $25 upon conviction. If within 30 days after the passage of the act any company now operating in the District shall not have changed its rates to conform with the foregoing, then the commissioners may permit any other company or companies to install a service, upon bond being filed to the amount of $100,000, and the assurance that it will maintain its service for a period of not less than five years.

Independent Telephone Movement in Indiana.

In the course of S. P. Sheerin's address before the city officials of Indianapolis recently in which he advocated granting an independent telephone company a franchise, he presented petitions signed by residents of the following named towns who desired to have the new company established, in order that they could have telephonic communication over independent lines with Indianapolis:

Franklin,	Huntington,
Elkhart,	Frankfort,
Elwood,	Bluffton,
Connersville,	Warsaw,
Cicero,	Middletown,
Bloomington	Worthington,
Rockville,	Pendleton
Danville,	Ft. Wayne,
Rushville	Veedersburg,
Noblesville	Dunkirk
Maplewood,	Greenfield,
Lizton,	Wabash,
Center Valley	Madison,
Pittsboro	Winamac,
Delphi,	Lagrange,
Hazelwood,	Rochester,
Shelbyville,	Hartford City,
Lebanon	Lafayette,
Logansport,	Cumberland
Greencastle	[illegible]
Cloverdale,	[illegible],
Roachdale,	Knightstown,
Bainbridge,	Winchester,
Plymouth,	Crawfordsville,
Columbus,	Annapolis,

It was claimed that these towns, according to the United States census of 1890, represented more than 900,000 persons.

The Telephone Situation.

By J. J. Nate.

Part II.

Toll Lines.

From the work thus far accomplished by the independent telephone companies in the way of territorial and interstate toll-line construction, it is clear that as an investment it is equal to, and, in some instances, better than, exchange construction.

At the present writing many thousands of miles of wire is in use by the independent companies over which tolls are being daily collected. A complete list of this mileage is not at hand, but the Western Electric and Union Telephone companies of Iowa are successfully operating to-day over a system, comprising fully 3,000 miles of line, the greater part of which they own, and their patrons are receiving good service throughout a territory embracing Iowa, Minnesota, South Dakota, Wisconsin and Nebraska. The same companies have recently completed an organization for the extension of their system to Kansas City, St. Louis and other principal points south and west, and have also secured a franchise for the construction and maintenance of toll lines and suitable terminal facilities in Minneapolis and St. Paul, and during the coming season will thoroughly reconstruct their lines so that the best of service can be furnished over the entire system from one end to the other, which, when completed, will pretty thoroughly take in the Mississippi Valley country.

In Pennsylvania and West Virginia another combination system of toll lines has been completed, and is in full operation to-day, comprising a total of over 1,600 miles of line, while in the states adjoining local companies are gradually reaching out with toll-line connections, and in a very short time a complete system of independent toll-line service for the entire southeastern portion of the country can be looked for.

Pennsylvania, Ohio, Indiana, Michigan, Wisconsin and Minnesota are all states in which the independent exchanges own and operate at the present time from 2,000 to 4,000 miles of toll lines. In the eastern states intervening points between independent exchanges are rapidly being covered. In the northern states the work is now going forward, and with the beginning of spring we have reason to believe that Duluth, Superior, Ashland and other Lake Superior points will all be in communication with the Mississippi Valley system. On the Pacific Coast we find a considerable mileage of independent toll lines, and in the South a greater percentage than one would imagine.

A telephone line equipped for toll service should be of the very best construction, the cost per mile varying somewhat according to the distance over which it is necessary to give good service and the nature of the country through which the line must pass. Even short lines between large towns should be of construction that can be made available for long-distance service. A line constructed of one No. 10 iron wire conductor (and nothing smaller should be used under any circumstances) would cost under ordinary conditions from $50 to $60 per mile, about as follows:

Thirty-five (30-foot) poles, five-inch tops......	$35.00
Two hundred and forty pounds of No. 10 B. B. galvanized wire at 3 cents per lb......	7.20
Brackets, glass and spikes..................	1.00
Distributing and setting poles...............	17.50
Stringing wire	2.00
Total	$62.70

The same line, if equipped with two No. 10 wires and six-foot cross-arms, would cost $75 per mile; if constructed of No. 12 hard-drawn copper, one wire, the line would cost $70 a mile, and with two wires, $100 per mile. These figures cover A-1 construction. As a matter of fact, many of the companies which have so far constructed territorial lines find that with the use of 25-foot poles at 25 to a mile, and using a No. 10 iron wire, it is possible under favorable conditions to construct a line at a cost of $40 per mile.

Many independent companies which were unable to appreciate the rapid growth of toll-line service constructed miles of toll lines using No. 12 iron wire. Actual tests show that good service could be given over such a line up to 100 miles, including from 15 to 20 stations, and these are the people who will find some reconstruction necessary in order to give service which will compete successfully with the Bell company's long-distance work. Loss of toll-line business has presented to the Bell company a problem which has received careful consideration and resulted in a decision to spend all the money necessary for the equipment and building of superior toll-lines, covering in many instances the identical territory over which they have furnished an inferior service for so many years. This move must not be lost sight of by the independent companies if they wish to retain the prestige gained through a generous support of the public at large, and, strange to say, an improved service.

There seems to be absolutely no question but that if independent companies of this country will furnish a satisfactory service, the support of the people can be relied upon. From statistics based upon actual work in toll-line service, it has been ascertained that 85 per cent. of the businesss transacted by 'phone is confined to one county and those immediately adjoining, while 10 per cent. is found to be within a radius of 200 miles; the other five per cent. may be considered extremely long-distance service between large cities, and which the independent companies have not thus far attempted to handle, nor is it at all necessary that they should. It needs but little argument on the part of an independent toll-line company to convince its customers that it covers fully all the territory necessary and is able to furnish an all-sufficient service at greatly reduced rates. In larger cities a demand exists for service over 1,000 miles of wire or more, but this demand is confined principally to large concerns with headquarters in great business centers, which can well afford to pay the high rates of toll asked for this class of service. How often does the doctor, lawyer or country merchant in smaller cities and towns find it necessary to call for points a thousand miles away? A telegraph message lets him out every time at an expense of 25 to 50 cents; anything over $1 for telephonic communication is not paid out by the people at large, except in very rare instances, such as in large money transactions, a sudden death or from an agent of a large company to headquarters. I think that we may safely say that the American Telephone and Telegraph company will successfully handle this business, and that those who wish to make use of that service will find it no hardship to hunt up the company's toll station in such an event. For years and years customers in smaller places found it necessary to go in person to the Western Union Telegraph company's office in order to send a telegraph message, and certainly an occasional visit to a long-distance station, supposing a man wishes to talk seven or eight hundred miles once or twice a year, is no hardship, and does not indicate the necessity of a Bell telephone in his place of business. A public-spirited man who is desirous of retaining at home money earned in his own community will support local enterprises, providing he is given satisfactory service, and unless he be a man of very large interests he will find as a matter of fact that his business is confined within a distance of 200 miles or such a matter, and is not only satisfied but anxious to patronize home industries, just as long as he gets value received. Therefore, long-distance telephony does not enter into the success of local independent enterprises, beyond an ability to satisfactorily deal with the problem, and the more thought given to this matter by those who are in doubt and the closer the investigation, the more certain will this fact become apparent.

One vital point in regard to toll-line construction has up to the present time been very largely lost sight of by the independent companies, and in consequence an evil is growing up which in the immediate future implies unnecessary expense and loss of business. I refer to the indifferent means employed to establish connections over the lines of the different local companies at interconnecting points. The apparatus at one exchange may be utterly unsuited for efficient service over the lines or the system of a neighboring exchange. This condition is largely due to the purchase of cheap and inferior material, which perhaps fairly answers the purposes of a small exchange, but is in no wise adequate to the work of toll-line service and the employment of men who do not understand these matters. There is a way out of these difficulties and it should be followed up at once.

Investment.

The telephone business requires attention and practical and expert knowledge in order to make it a success. Like any other business, its affairs may be properly managed by men of good business ability, but its operative work and the many details incident thereto must be superintended and cared for by men who are conversant with the business, or needless expense will run the cost of maintenance so high that "earnings surplus" will be very nearly if not entirely wiped out. Profits are large in the business, barring accidents, which 99 times out of 100 are the result of carelessness. Promoters should not lose sight of the risk they are taking when their construction work is indifferently performed or their employes careless. One verdict for $5,000, the consequence of an accidental death, due to an open post-hole or defective cross-arm or bungling work in the handling of large poles, will most effectually wipe out net profits for a long time. A man is most certainly "penny wise and pound foolish" who entrusts construction work to men who are inexperienced and necessarily incompetent.

Toll-line earnings vary according to rates. The independent companies of the country as a rule have practically cut the Bell rates in half, and even then are doing very nicely indeed and are well satisfied. I have been told of one line in particular, costing about $4,000, that is and has been for over a year earning $10 per day net. Needless to say, this is an unusual condition. Another company of which I have personal knowledge has invested to date about $60,000 and is now collecting for tolls over $1,500 per month. It has found about 20 per cent. net thus far on the investment. The business is so good that men known and recognized as men of ability and prominence are devoting their entire time and attention to telephone interests.

Novel High-tension Series Enclosed Arc System.

By J. H. Hallberg, E. E.

Many articles have appeared in the pages of this journal describing the enclosed arc lamps and calling attention to their many advantages, but the writer has not seen any particular attention called to the high-tension series enclosed arc lamps

I will first take up a few questions as to the requirements of the enclosed arc lamp for high-tension series street lighting and commercial circuits. The insulation should consist of mica, lava and porcelain; fiber should never be used in arc lamps, except for switch handles. When testing insulation it is best not to depend on the ringing of a magneto bell. Take one wire from the magneto in operation and connect to the ground or to the frame of dynamo or cover of lamp. Then the other wire should be attached to a small handle and taken in one hand. With the other hand touch some connection or bare wire in sure contact with circuit. To be perfectly sure the hands should be wet. It is understood that the operator must be insulated from the ground. I have found this method to be the surest where no special testing apparatus is at hand, as you will surely feel the current from the magneto if there is a leak. Never depend on ordinary insulation in high-tension series lighting, as the extremely high pressure of the "kicks" caused by flashing of the dynamo or the breaking of a wire will break through any ordinary insulation and consequently ground lamps and apparatus. The lamps should be provided with a standard hanger and so designed that they will fit in the majority or hoods with hanger-boards now in use. The lamp should be provided with a cover that can be easily removed for inspection. The lamp should be snow, rain and as nearly dustproof as possible and at the same time ventilated. All parts should be easily interchangeable with the use of no other tool than a pair of pliers and a screwdriver. My experience has been that it is better to use binding-posts and connectors than solder, for various reasons, the main one being that a coil can be changed without the troublesome use of a soldering iron. The cut-out should be positive in its action and have a sure adjustment, and its contact points should be easily interchangeable. It is preferable that the clutch should work directly on the carbon, as the wear of the clutch is thus reduced on account of the softness of the carbon. The lamp should be equipped with some device to prevent the slipping of the carbons. In a differential lamp the slipping could only happen during its burning, as the carbons are together during the day or when the lamp is not working. In a shunt-wound lamp the device should always be in action, as the carbons in a shunt lamp are always apart except at the moment that the arc is struck. This device may seem unnecessary, but experience has proven that the best of clutches will slip in stormy weather, especially on lamps placed on tall poles, or if they are suspended from poles which also carry one or more trolley wires.

The inner globe should be easily interchangeable, as when trimming a number of lamps it is demonstrated that it is best to exchange the dirty inner globes for clean ones, and bring the dirty globes and what is left of the upper carbon back to the station, where the former are cleaned and the carbons are cut to the right sizes for negative or lower carbons for the next trimming. The lamp could be so designed that it would maintain the same voltage at the terminals and arc, whether the amperes be four or seven, varying, or any constant between these two numbers. A lamp designed for four amperes should operate on any amperage between four and seven. The arc in the lamp should consume the entire voltage as measured at hangers except one volt. This one volt is all that is necessary to hold the cut-out open. When the lamp is cut out automatically not over four volts should be expended when lamp coils are hot. The shunt coil and cut-out should not consume over one-tenth ampere when the lamp is hot. If possible, the lamp should be so designed that no dash pot or spring would be required in its mechanism. This is very important; most station managers have probably experienced more or less trouble from dirty dash pots, feed and cut-out springs. In many cases these lose their tension, which would either keep the lamp out entirely, or destroy all adjustment, allowing the lamps to burn 30 to 70 volts, instead of 45 to 50. The writer knows of some cut outs that would not shunt the lamp until the arc reached about 140 volts. This, of course, would burn the shunt coils in the lamp, as they were only designed to stand a maximum of 70 volts. I believe all will agree that a spring and a dash pot are the most frequent causes of trouble on a high tension street lamp, which is subjected to internal heat and to dust and dampness. The lamp should be of light weight, say 25 pounds, complete with hood, hanger board and globe, so as to allow the use of lighter construction and suspensions; a light lamp will also make the old balancing weight unnecessary, and on shipments of lamps the freight is about one-half of that paid for old-type long and heavy lamp. The lamp should be adapted for either inside or outside service without change; at the same time they should be so designed that if necessary the plain cover can be substituted for a fancy one without any changes on the lamp. The lamp should be as short as possible, say, about 34 inches from top of hanger to bottom of globe, so as to allow the lamp to be used in low-studded buildings, basements and hallways. If it should be necessary to have a long lamp in order to suit some particular customer, it can be done by simply putting on a longer cover without changing the mechanism or the globes. The lamp should regulate so that its voltage would not vary over five volts at any time from normal. The lamp that is designed and built so as to come up to the specifications should certainly meet with the approval of most station managers and electrical engineers. Since the invention and perfection of the enclosed arc lamp it is possible to build a lamp of the type mentioned, and the writer, after personally handling nearly 100 of them for street-lighting purposes during the last 10 months, has come to the conclusion that it is the most convenient street lamp and will surely occupy a prominent position among the enclosed arc lamps, as it possesses higher efficiency than any other type of enclosed arc lamp as yet advertised in the country. The light from the high-tension enclosed series arc lamp possesses all the advantages that are so noticeable in the low-tension direct-current enclosed lamp, which are a perfectly steady light, perfect diffusion and distribution, the tint of which can be governed by the use of different combinations of globes. It burns from 100 to 150 hours with one 12 by one-half inch solid (imported) carbon. This not only saves labor in trimming and attention, but the lamp mechanism and clutch does not wear, as the lamp feeds only a few times every 12 hours. It must also be remembered that the clutch works on the soft carbon, which prevents it from wearing, and as there are no carbon rods, the repairs on an enclosed arc lamp are only about 10 per cent. of that for the open-arc system. If we now get such a lamp it would be perfectly proper to ask the following question, if you do not already realize the economy of a plant equipped with this type of lamp for street lighting: How do these lamps compare with the open-arc system in regard to amperes, voltage and candle power? The old type open-arc lamp requires 10 amperes and 45 to 50 volts (equal to 500 watts) to produce what is known as 2,000 nominal candle power. The new enclosed arc lamp with clear globes requires seven amperes and about 71½ volts (equal to 500 watts) to produce 2,000 nominal candle power. From the figures given it can be seen that the wattage remains the same for both types of lamps: consequently the coal bill is not increased when the enclosed series lamps are used. The enclosed arc lamps require about 30 per cent. higher voltage, but the amperage may be reduced accordingly. I consider this a great advantage, especially if your circuits are very long, as the line loss would be cut down considerably. If you desire a 1,200 candle power system your wattage consumption would be about 300 to 325 (equal to four amperes and 80 volts, or five amperes and from 60 to 70 volts). I mentioned in the early part of the article that a shunt-wound high-tension enclosed series arc lamp could be so designed that it would operate with the same arc voltage, even though the amperes vary about 40 per cent. The advantage of this will undoubtedly be seen. To-day it will be found that almost any manufacturer of arc dynamos will furnish regulators and controllers, by the adjustment of which you may change the amperage from, say, 4½ to 6½ amperes, and the dynamos will hold their amperes very steadly at any point. This enables you to get a perfectly controllable arc circuit, which may be varied at will from the station.

On dark nights you may run your dynamo at seven amperes. The next night may be moonlight, then you can cut your dynamo down to say five or six amperes; then, during winter, when snow is on the ground, you will not over, say, 5½ amperes during the darkest nights. On moonlight nights, with snow on the ground, you could probably go as low as 4½ amperes on your circuit and still you would light your streets equally as well as you would on a very dark night with seven amperes. This feature of this system will save a station or a town a good many dollars. Figures show the following:

200 lamps at 70 volts each = 14,000 volts and seven amperes = 98,000 watts.

200 lamps at 70 volts each = 14,000 volts and 4½ amperes = 63,000 watts.

This shows a saving of 35,000 watts per hour. If your plant can produce one electrical horse power per hour with four pounds of coal, you would save during an 11 hour run on 4½ amperes instead of seven amperes about one ton of coal, equal to, say, about $2. By applying this system I am sure a great many managers who now shut down at 12 p. m. could persuade the town which they light to pay a little more and run on a very low amperage the rest of the night, and then it might be profitable to run an all night incandescent circuit. I am sure lighting plants in small towns could get many new customers on their incandescent circuit if they could afford to run until daylight instead of shutting down at 12 p. m. These are only a few examples showing the many advantages that can be gained through the use of this system. There are many stations which have four to seven ampere dynamos that are not in use. For, as the town grows, the requirement changes, a larger light is wanted, and a 10 ampere arc system has to be put in. Now clean and fix up your old four to seven-ampere dynamos, write for information to arc lamp manufacturers who make a high-tension series enclosed arc lamp. Be sure that the manufacturers guarantee the lamp to burn on a varying amperage of say about three, without change in the voltage at hangers, as your old-type dynamo may not regulate as well as the later designed and improved lamps. So you see, if the town board should vote to put in 15 or 20 new 2,000 candle power arc lamps, and your present 10-ampere dynamos are loaded, you can, if you have an old 6½-ampere dynamo, by simply buying this type of lamp and putting up new circuit, furnish this town with this lamp and save the cost of a new dynamo. The foregoing explanations and suggestions might alone show station managers how they would profit by the use of an arc lamp of this type, but I will now call your attention to the most important fact, and that is, that this lamp operates for 125 hours without any attention or trimming. At each trimming there is only used one 12 by one-half-inch ("solid imported") carbon. The cost of this quality of carbon is between $27 and $30 per thousand; consequently a lamp of this kind, if operated 10 hours every night in the year, will consume 30 of these carbons per year, equal at highest carbon price to 90 cents. If your carbons for the old type open-arc lamp cost you $15 per thousand pair, delivered (this is certainly the lowest cost figure), then a lamp of that type which consumes one pair of carbons each night of 10 hours requires 365 pairs for one year, equal to $5.47½, and making a saving of $4.57½ each year per lamp in carbons alone.

As the enclosed arc only needs trimming once every 10 or 15 days, one or more trimmers may be dispensed with. The enclosed arc having an inner globe, a deduction of about $1 per year for each lamp might be made from the above figures to allow for the additional chances of breakage.

Badt Hermetic Cell.

The accompanying cuts illustrate the Badt hermetic cell which has only recently been placed upon the market, but which has been the object of much interest among primary-battery men who have been acquainted with the experiments conducted by Lieutenant F. B. Badt in perfecting it. It is an

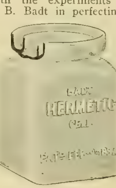


Fig. 1.

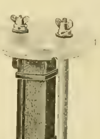

Fig. 2.

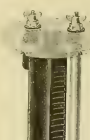

Fig. 3.

BADT HERMETIC CELL.

air tight open-circuit cell with oil seal and with oil insulation. The claims for this new cell are strikingly presented in the following list of negative qualities: No evaporation, no creeping of salts, no leakage of electricity, no premature disintegration of zincs, no trouble of any kind, no attention, no attendance, no repair bills. Finally, it is claimed that while it is "expensive in first cost" it is "cheap in the long run."

The manufacturers of the Badt hermetic cell direct attention to many of the failings common to cells of this class which it is claimed are overcome in the Badt cell. All who have had experience in handling primary batteries realize the annoyance caused by evaporation of the liquid and the creeping of salts. This creeping of salts is usually started by the evaporation of the liquid. If there is no creeping of salt, of course there will be no danger from short circuiting of the electrodes within the cell.

The advantage gained by maintaining a uniform level of the solution is easily seen by observing a wooden post driven into the river. The wood will rot there where it is exposed alternately to the air and to the water, namely, near the surface of the water. A similar action takes place in an electric cell where the zinc often is found eaten through and used up only where the gradual sinking of the level of the solution has exposed portions to the influence of various chemical and electro-chemical agencies. Experience shows that with the surface of the solu

tion kept at the same level, this zinc-destroying effect will not take place. The oil seal absolutely insulates the glass cover from the jar, and as no salt can creep over the oil, the cover with its electrodes may be said to be insulated by means of an oil insulator from the jar and from earth. The cover, being of glass, insulates the electrodes from each other.

Fig. 1 represents the glass jar without cover, showing a part broken away, disclosing the channel or trough surrounding the upper edge of the jar. This trough in practice is filled with oil. Fig. 2 represents the glass cover with electrodes of cell No. 1 (hermetic prism cell). The cover is provided with two rims or flanges. The inner flange rests in the oil trough and the outer flange surrounds the top of the jar and prevents dust from getting into the oil trough. There are three notches at the lower edge of the inner flange to prevent the displacement of the oil in the trough by either internal or external pressure due to the electro-chemical action in the cell. Each electrode (zinc and carbon) has a shoulder carrying a metal terminal which passes through a hole of the cover, and soft rubber washers are placed on these terminals below and above the glass, in order to make the holes air-tight. Fig. 3 represents the glass cover with electrodes of Cell No. 2 (hermetic cell without prism or chemical depolarizer). The glass cover is identical with that for cell No. 1, so is the zinc; the carbon, however, is of a peculiar shape and has no prism (chemical depolarizer) attached to it.

This cell is placed on the market by Meysenburg & Badt of Chicago.

Extensive Railway Project.

The City Council of Kenosha, Wis., passed an ordinance at its last meeting granting a franchise for an electric railway through that town. This line will form a part of the system of trolley lines that it is proposed to build in Illinois and Wisconsin, and it is now claimed that a right of way has been secured between Chicago and Green Bay, Wis., a distance of 201 miles. The proposed line will parallel the Milwaukee division of the Chicago and Northwestern Railroad company.

The promoters say that by far the greater part of the route is covered by tracks, and that the Kenosha franchise was the last required to complete the right of way. About 60 miles of the track of the Fox River line, connecting Milwaukee and Green Bay, was laid last summer and fall, and many miles of construction work were completed during the winter. The Milwaukee, Racine and Kenosha electric railway is in operation from Milwaukee to the Kenosha city limits on the north, covering a distance of 35 miles. Another piece of the system is an electric line connecting Waukegan and North Chicago, lying four miles to the south of Waukegan. Between Waukegan and Evanston a good many miles of track have been laid. The distance from Evanston to Chicago, as is well known to Chicago people, is covered by the Chicago North Shore Electric and the Chicago, Milwaukee and St. Paul. Though the latter road is to be operated by steam, it is soon to be equipped with electricity, so that an entrance to Chicago from Evanston can probably be secured without great difficulty.

The charter of the Milwaukee, Racine and Kenosha road permits the carrying of passengers, baggage and express, and it is understood that the Fox River line between Milwaukee and Green Bay intends doing a freight business also. Its passenger cars are almost as heavy as an ordinary steam-railway coach and they are equipped with motors of double the power of those used on the ordinary electric railway coach. The Milwaukee, Racine and Kenosha company is now operating nine cars, one every hour, between Milwaukee and Kenosha. It charges half the fare of the Chicago and Northwestern, but the service is much slower.

The Kenosha franchise provides for a local system requiring the construction of about five miles of single track in addition to the laying of the tracks to be used by the through line.

Public Service in Indianapolis.

The Indianapolis council committee on contracts and franchises met in private session March 3d to consider an ordinance which makes sweeping reductions in the price of electric lights. W. L. Taylor, the lighting company's attorney, was present and addressed the council, contending that the company has a fixed franchise for four more years, at the end of which time any regulation that the city deems right may be imposed, and that the fact that the company pays a percentage of its earnings into the city treasury, which no other company enjoying public rights does, should entitle it to some consideration. No action was taken.

The council committee on public safety and comfort killed Mr. Schaffer's ordinance requiring at least ten electric bells on every street car with which to signal the motorman. Two members held the opinion that these bells would probably lead to an abandonment of [illegible] whom they regarded as very useful functionaries. One member said he went to Chicago to ask about a similar ordinance there, and was told by street car men that it resulted in endless confusion and many unnecessary stops, owing to mistakes of those who did not know how to operate the bells properly.

Amateur Model-making Competition at the New York Exposition.

A committee consisting of Prof. Morris Loeb, Dr. C. A. Doremus, Dr. W. E. Geyer and T. C. Martin has drawn up rules and regulations for an amateur model-making competition in connection with the electrical exhibition to be held in New York in May. Printed forms can be had from the management, 15 Cortlandt street. The classes are given below, each class having prizes not to exceed $50 and bronze medals, the exhibits to be judged by a committee of five well-known men. It is believed that the contest will awaken general interest and elicit some beautiful and interesting apparatus. There are a great many young people and students who find pleasure in handiwork of this character. The exhibits must be entered a week before the exhibition begins. The classes are as follows:

Class A—Working model or actual machine of a dynamo-electric or electro-dynamic type, made by one or more boys under 21, so far as designing, lathe work, assembling and finishing is concerned.

Class B—Instrument of precision, made by amateur or student, including galvanometers, resistance bridges, etc.

Class C—Practical application of electricity to communication, the assembling and finishing to have been the work of a single exhibitor.

Class D—Ingenious application of electrical appliances to domestic, etc., uses by an amateur under 18; none of the apparatus to be necessarily of home manufacture.

Class E—Design or working drawing of an electrical appliance or installation, made within the past twelvemonth by a student of a recognized chartered institution, and bearing the instructor's certificate as to its bona fides.

Class F—Design or instrument made by a teacher, below the grade of college professor, for illustrating some electrical law.

CORRESPONDENCE.

New York Notes.

New York, March 14.—By a decision of the Appellate Division of the Supreme Court, handed down on Friday, the Rapid Transit Commission is placed in a much better position with reference to its tunnel plan of rapid transit. The court had held that the contractor for the road must furnish a $15,000,000 bond, but this requirement is now interpreted to mean that only $1,000,000 of the bond shall be a continuing security during the whole life of the contract, the other $14,000,000 being required to cover the period of construction and equipment. This judicial interpretation makes it much more likely that bids to build and operate the road will be received. A. B. Boardman, one of the counsel for the Rapid Transit Commission, said that he considered the decision as an important victory for the underground tunnel plan. He saw no reason why the commission should not in due time proceed to advertise for bids for the contract, and was confident that there would be no difficulty in securing trustworthy and responsible contractors to furnish the $14,000,000 bond for the period of construction and the continuous bond for $1,000,000. Mr. Delafield, the secretary of the commission, thinks that the bond, as now provided for, is not prohibitory. He stated that he could not say how soon the commission would act in the matter or when its next meeting would take place. Mr. Delafield said that the decision would in no way affect the matter of the application of the Manhattan Elevated Railway company, which would be decided upon its own merits. He added that the Rapid Transit Commission would probably move definitely within a week or 10 days.

What is an "electrolysis sanitarium?" I am moved to ask the question by this item in a daily paper: "John L. Baker has been appointed receiver for Dr. Fort's Electrolysis Sanitarium by Justice Fursman of the Supreme Court in proceedings begun several months ago for the dissolution of the corporation. The assets are $476 and the liabilities $150. Mr. Baker was vice-president of the concern." Perhaps some of the western electrical men can answer the question.

P. H. Flynn, the Brooklyn trolley magnate, who recently caused the Coney Island and Brooklyn Railroad company to be permanently enjoined from executing a mortgage on its property amounting to $1,500,000, has obtained a temporary injunction from Justice Dickey of the Supreme Court, preventing the company from increasing its capital stock from $1,000,000 to $2,000,000, or from issuing or exchanging any such shares of stock. Mr. Flynn averred in his complaint that it was intended to manipulate the securities to the detriment of the minority stockholders. This litigation will have the effect of postponing the proposed consolidation of the Coney Island and De Kalb avenue roads, and may, it is said, block it altogether. The roads have been operated jointly under a lease for nearly a year, and the plans for consolidation were about perfected a few weeks ago.

E. H. Lewis, representing the Edison company of this city, appeared before an Assembly committee recently in opposition to "Young Tim" Sullivan's bill fixing the price per hour for incandescent lights at three-quarters of a cent and for arc lights at four cents. It developed that "Young Tim" did not know the prices now charged, and the committe was amused when Mr. Lewis showed that the average price charged for these lights was lower than the prices fixed in the Sullivan bill. Mr. Lewis asserted that there was no demand for the measure from anyone but "Young Tim" and his cousin, "Big Tim," the senator, who has introduced a similar bill in the Senate.

The annual meeting of the Long Island Electric Railway company was held last week and the following-named officers were elected for the ensuing year: President, A. R. Hart of Brooklyn; vice-president, Charles A. Porter of Philadelphia; treasurer, William L. Wood of Jamaica; secretary, J. C. von Arx of Brooklyn. The following-named directors were chosen: Charles A. Porter, Jr., of Philadelphia, F. M. Harris of Philadelphia, A. G. Greenberg and Joseph Hogan of New York and H. A. Van Allen of Jamaica. M. S.

Canadian Intelligence.

Ottawa, March 12.—Two companies will apply to the Canadian Parliament, at its present session, for charters to supply electricity and run electric railways above Dawson City and throughout the Yukon district generally.

The promoters of the St. Thomas (Ont.) street railway have let the contracts for construction work, and they hope to have the road in operation early in the summer. At a meeting held last week the company authorized the issue of debentures for the amount of $50,000.

The Dawson City Electric company is applying to the Dominion Parliament for an act of incorporation. The company asks to supply electric light, heat or power throughout the city, and within a radius of 200 miles, as well as to operate an electric tramway.

J. D. Oligny, contractor of Montreal, is an unhappy inventor. He had spent much time on the invention and construction of an incinerator, and a public test was to have taken place this week, but previously a fire started in an old slaughter house at Cote St. Paul, where the incinerator was housed, and now nothing is left of it but a wreck. Mr. Oligny represented that he could destroy garbage by means of electricity and a certain solution which hastened decomposition. It did not matter whether the garbage was ashes, metal or stone, all would be destroyed, but the inventor did not make his incinerator fireproof, with the result noted. Mr Oligny expects to repair the machine for a proper test.

The Dominion government will be asked to make an appropriation, at the present session of Parliament, for the extension of the government telegraph system to the Yukon country. At the present time the government telegraph line extends from Ashcroft, B. C., to Quesnelle, a distance of 225 miles. From the latter point to Telegraph Creek is 54 miles. The proposal is to build the section to Teslin Lake next season, reaching the Yukon in 1899. The cost is roughly estimated at $500,000.

The Canadian Pacific Railroad Telegraph company now proposes to stretch a copper telegraph wire from Montreal to Vancouver, B. C. It will then be possible to sit in the Montreal office and transmit messages to Vancouver direct. The wire to be used will weigh 300 pounds to the mile, and the total weight of copper wire to be used will be something like 450 tons. Work is expected to be begun on the new line on the 1st of April next, and it is hoped to have the line completed and in working order by the 1st of June. Construction work will commence at the Montreal end. The copper wire to be used in the enterprise will cost in the neighborhood of $250,000. The wire will be worked duplex.

Quebec's electric street railway is about to change hands. It appears that when H. J. Beemer transferred the franchise to the present company he retained a two-years' option of the property, which he now insists on availing himself of. It is said that the company offered $300,000 to buy out his right, but that he demanded $350,000, which it would not pay, and now he is about to redeem the property, paying the company 10 per cent. premium on the cost of construction and six per cent. interest on the money invested, as agreed at the time of the transfer. It is understood that the returns of the road have been so handsome that Mr. Beemer has found no difficulty in selling to another company, which will also take over the Quebec and Montmorency railway, consolidating the two lines and running them both by electricity. A. V. W.

Northwestern Notations.

Minneapolis, March 14.—The town of Alden, Ia., may secure electric lights soon, as there is a man with capital ready to put in a plant as soon as a franchise is granted.

O. B. Durdall has made a proposition to the council of Algona, Ia., to establish an electric-light plant, and the city will vote at the city election on granting him a franchise.

The council of Duluth, Minn., will proceed at once to carry out the platform on which it was elected, the ownership of all municipal franchises. A committee has been appointed to negotiate with the Commercial Light and Power company and the Duluth Light and Water company, the latter operating in West Duluth, for the purchase of their

franchises. The committee was given power to draw plans for paralleling both systems in case the companies refuse to sell at a price that meets the idea of the committee.

It has been erroneously reported that Mitchellville, Ia., will bond itself for $10,000 for an electric-light plant.

Bittner & Lynch have been granted a franchise at Heron Lake, Minn., for an electric-light plant.

The project of an electric-light plant for West Point, Ia., is being agitated.

Gaylord, Minn., voted for electric lights by almost two to one.

The stock in the Mankato Gas and Electric Light company at Mankato, Minn., held by R. D. Hubbard, has been turned over to John B. Meagher, by Mr. Hubbard's assignee, George M. Palmer. The Gas and Electric company proposes now to expend $10,000 this season in improvements to its plant.

On March 28th the city of Boone, Ia., will vote on establishing a municipal electric plant.

The Fox River Valley Interurban Railway company has completed a survey for its proposed line from Neenah to Oshkosh, Wis., 13 miles. The line is to be part of a road that is eventually to be extended to Milwaukee. The line between Neenah and Appleton is expected to be in operation by April 1st.

W. J. Bonwell of St. Paul has gone West to put in the electric-lighting plants for the Cascade tunnel being constructed near Seattle, Wash., for the Great Northern railway.

A slimly attended mass meeting in Red Lake Falls, Minn., declared in favor of an electric-light plant. Marcus Johnson is an applicant for a franchise, and proposes to run a plant in connection with the flour mill. C.

PERSONAL.

Mr. C. D. Crandall, the general manager of the Western Electric company, has returned from his southern trip.

A. C. Garrison, secretary and treasurer of the Columbia Incandescent Lamp company of St. Louis, is in the East on business connected with the company in New York, Baltimore and Pittsburg.

Mr. E. E. Keller, the vice-president and general manager of the Westinghouse Machine company of Pittsburg, delighted his Chicago friends by a visit during the week. Mr. Keller was accompanied by Mr. T. L. Brown, the treasurer of the company, and the gentlemen inspected the factory at Craigin.

Henry L. Doherty, general manager of the Madison (Wis.) Gas and Electric Light company, was in Chicago last Saturday. Mr. Doherty is spending considerable time in Columbus, Ohio, where the interests with which he is associated have recently gained control of the electric-lighting business.

James W. Johnson is again connected with the Chicago office of the General Electric company, acting as special agent. Mr. Johnson is one of the well-known electrical men of the West, having an electrical experience in Chicago dating 10 years back. From 1888 to 1894 he figured prominently in the western business of the Thomson-Houston and General Electric companies, having charge of the lighting department of the latter at the time of his resignation four years ago. Mr. Johnson has taken an honorable part in the electrical development of the West, and now that he is back among old friends he may be depended upon to actively participate in the work of extending the general electrical trade with returning business prosperity.

ELECTRICAL SECURITIES.

The Edison Electric Illuminating company of Brooklyn reports gross earnings for February $75,601, an increase of $5,783; operating expenses, $38,975, an increase of $1,160, and net earnings $36,625, a gain of $4,622 over February of 1897.

The minority stockholders of the Wilmington City Electric Railway company have accepted the proposition to sell their stock to the Clark syndicate at $13 a share, payable in five per cent. gold bonds, and the deal has been closed.

At the meeting of the stockholders of the Allegheny County Light company of Pittsburg it was voted to increase the capital stock from $1,500,000 to $2,500,000. The increase is to be applied to extending the company' lines, enlarging the plant and for general betterments.

The Bridgeport Traction company reports gross earnings for February of $21,671, an increase of $188 as compared with the same month of last year, and net $7,117, an increase of $1,003. For the eight months ended February 28th the gross earnings were $222,073, an increase of $6,950 as compared with the corresponding period of last year, and net $103,835, an increase of $16,840.

A mortgage for $750,000 has been given by the Union Light and Power company of Salt Lake City to the Central Trust company of New York. The mortgage covers all the real and personal property, improvements, lighting and power plants, pole lines and franchises of the Union Light and Power company, and is given to secure the payment of 750 consolidation mortgage bonds of the denomination of $1,000 each, bearing five per cent. annual interest, due in 20 years at 105. The money will be used to take up old bond issues bearing six per cent., and for improvements to the company's properties.

A gentleman identified with the Union Traction company of Philadelphia says that since March 1st the daily gross receipts of the system have been $2,500 ahead of last year. For the eight months of the fiscal year, or up to the close of February, the company earned within about $75,000 of the charges for that period. The net earnings for the period are a gain of about $600,000 over the corresponding eight months of 1896-97. The gentleman says that February is one of the worst months of the year, and that with the four good months following there is excellent prospect that Union Traction will show for the year ending June 30th something earned over fixed charges as compared with a deficit last year of $850,000.

The report of the Western Union Telegraph company for the first quarter of 1898, ending March 31st, shows net revenues based upon nearly completed returns for January, partial returns for February and estimated business for March, of $1,200,000, which, added to surplus of $8,023,239.88 on hand January 1, 1898, makes the total amount available $9,223,239.88. From this amount there is appropriated for interest on bonds $224,420 and for sinking fund $9,991, a total of $234,411. In addition to this amount there is required for the dividend of $1\frac{1}{4}$ per cent. on capital stock issued about $1,216,980, which leaves a total net surplus, after these deductions, of $7,771,848.88. For the purpose of the quarterly dividend, to be paid on April 15th, the books of the company will be closed March 18th, and will reopen on the morning of the first day of April next.

TRADE NEWS.

The report of the Chicago Electrical association committee on standard diagrams has been published in concise, convenient form for the use of electrical draftsmen and patent attorneys. Application for copies should be made to J. R. Cravath, secretary of the organization.

W. R. Garton, 414 Ashland block, Chicago, has been appointed western representative of the Keystone Electrical Instrument company of Philadelphia. The Keystone company has been rushed with business since the first of the year, and is preparing to increase its facilities.

"The rapid growth of our business is the strongest evidence of the superiority of our mica," appears as a preface to the 1898 catalogue of mica specialties which has been mailed to the electrical trade throughout the United States by Eugene Munsell & Co. of New York and Chicago.

J. W. Hull, representing the Cabinet Manufacturing company of Steubenville, Ohio, is stopping at the Palmer House, Chicago. Mr. Hull is energetically pushing the interests of his company and has met with flattering success. The company manufactures woodwork for telephone manufacturers and others, and it is said that it turns out none but the best work. Mr. Hull has already secured a number of Chicago orders.

It will be interesting to the readers of the Western Electrician to know that Mr. E. J. Wessels, who for several years was general manager of the Standard Air Brake company, has recently become proprietor of a weekly journal, which will be called the Universe, being devoted to business men and women, and covering the various important subjects of the day, with a number of important departments, covering the arts and sciences. The first issue presents a number of interesting articles and argues well for the future success of the venture.

H. M. Grant, who for the past 18 years has been general sales agent for the Vulcanized Fiber company, severed his connection with that concern on February 1st and accepted a similar position with the American Hard Fiber company of Newark, Del. Mr. Grant is known in every branch of the electrical trade, having traveled from the Atlantic to the Pacific Coast, and personally called upon the various concerns who use hard fiber. Success has attended his efforts, as is shown by the business which the concern he was formerly connected with has secured. The American Hard Fiber company is to be congratulated in securing the services of a gentleman who is so justly popular, and he will undoubtedly achieve a continuation of his former success in his new business connection.

Independent telephone companies will be interested in the announcement of the Hawkeye Telephone Construction company which has been formed to build and equip telephone exchanges and toll lines. The company says: "To successfully compete with the Bell monopoly, you must furnish the best service possible. We will construct your exchange complete, from conduits and poles to switchboard and telephones, or will install either the central office or outside system separately. We will operate plants constructed by us for 30, 60, or 90 days, in order to give you satisfactory proof that our work, which will be done under the personal supervision of C. W. Barthen, is of the very best." Estimates will be furnished for switchboards, telephones, toll lines, overhead and underground systems, in part or complete. The company has offices at Chicago and Des Moines.

The Davis & Egan Machine Tool company of Cincinnati, Ohio, has just received through its office at Berlin, Germany, orders from the Gewerkschaft Deutscher Kaiser at Bruckhausen (Rhenish Prussia) for 14 machines, including lathes, planers, shapers drill-presses. This is the largest steel works in Germany. The Cincinnati company has also received through the same office an order from the Internationale Bohrgesellschaft for 12 lathes and 12 drill-presses. The company is now running its Cincinnati plants day and night, and the plant which it recently purchased in Covington, just across the river, will be in full operation within the next two weeks.

The Peru (Ind.) Electric Manufacturing company is again preparing for the erection of another one and two-story building. It is to be 25 feet wide and 70 feet long. The structure will be made of brick with either an iron or a slate roof. The clay bins will be moved into the new building and the space made vacant will be filled with porcelain presses. The two-story part of the new building will be made fireproof, to contain all the dies used in the business. A porcelain kiln, surrounded by an ironclad building 30 feet square and one story high, has just been completed and will soon be pressed into service. This makes five kilns for the works. At present the company is enjoying a boom in trade and has a force of nearly a hundred persons at work. The present officers of the company are: President, J. O. Cole; vice-president, C. H. Brownell; secretary and treasurer, R. H. Bouslog; directors, R. A. Edwards, J. O. Cole, C. H. Brownell, J. G. Brackenridge, William Levi and William B. McClintic.

The management of the International Correspondence Schools of Scranton, Pa., has exhibited its customary enterprise in a new plan of calling public attention to the work of the schools. A handsome railroad car for the schools will shortly be sent on a tour through the principal manufacturing cities of the country. The length of the body is 50 feet and the width nine feet and eight inches over the sills. It contains a reception room, 18 feet long, furnished in quartered oak and fitted with bookcases, center table, wicker chairs, couch, carpet, curtains, etc. There are four sleeping sections of upper and lower berths, eight in all, occupying 12 feet six inches of the length, giving sleeping accommodations for eight persons. There is a storage room for books, and a saloon. The president of the schools, Mr. R. J. Foster, will be in charge of the car on its initial trip. His assistant, Mr. John G. Forsyth, will be in charge of the corps of six representatives, who will accompany the car. The plan of work proposed to be followed is to locate the car for a time in the immediate vicinity of large manufacturing establishments and afford to those interested a practical demonstration of the methods in which the work of the schools is carried on.

BUSINESS.

A little battery catalogue has been issued by the Peru Electric Manufacturing company of Peru, Ind. New types of Laclede and Hercules cells are shown.

The K. & W. company of Pittsfield, Mass., reports a rapidly increasing demand for its cut-outs, hanger-boards and dynamo brushes. Testimonials show the high regard in which these specialties are held.

The Pacific Electric company of La Crosse, Wis., advises its friends to color their own incandescent lamps with "Karsline;" to etch their own lamps with "Inline" and to finish their own fixtures with "Playtone." A circular giving prices and information is sent on request.

William C. Hubbard, vice-president and general manager of the Electric Arc Light company of New York, has just returned from a month's trip through the West and Northwest. Mr. Hubbard booked some good orders while away, and made a number of valuable connections for the "Pioneer" company.

Excellent catalogues of automatic switches, motor starters, knife switches and switchboard fittings are issued by Zindars & Hunt, manufacturers of electric-light and power specialties, 127 Fifth avenue, New York. The marbleized covers of the pamphlets are striking, and the contents are well arranged with very good illustrations.

Hans Swoboda, the electrician of the General Incandescent Arc Light company of New York, has been producing excellent results with an alternating enclosed arc lamp upon which he has been at work for a long time. The high state of perfection that he has attained for this lamp reflects great credit upon his ability in this class of work.

The D. A. Kusel Telephone and Electric Manufacturing company of St. Louis has received the contract to furnish the Farmington Telephone company at Farmington, Mo., with a 100-drop switchboard and 80 telephones. Thirty-five of the D. A. Kusel long-distance telephones have been sold for the line from Mokane to Jefferson City, Mo.

There has been some criticism by several men living north of Chicago in regard to the Western

Electric company advertising a swinging tree insulator when the snow was on the ground, but now is the time for at least 50 per cent. of the central stations in the United States to look after their outside lines and prevent them from coming in contact with trees.

The Hartford City Gas Light company of Hartford, Conn., has placed another contract with the Berlin Iron Bridge company of East Berlin, Conn., for one of the latter's steel roofs lined with patent anti-condensation fireproof roof lining, which has given the Gas Light company eminent satisfaction in the past. The new building is about 35 feet wide and 70 feet long.

On request the Farr Telephone and Construction Supply company of Chicago will send without charge its combined catalogue and hand-book of telephone information. This little book contains practical instructions about the building and maintenance of telephone exchanges and lines, with diagrams of connections, weight and resistance of wires, building estimates, information about patents, etc.

Superintendent H. T. Knight of the Connecticut Telephone and Electric company of Meriden, Conn., accompanied by the electrician of the company, C. E. Egan, has been visiting in New York for several days. The gentlemen named will also visit other eastern cities before they return to Meriden. They report that their concern has been rushed with orders during the last six months, and now extensive preparations are being made to take care of double the amount of business which was handled during the last year. The excellence of the products of the Connecticut Telephone and Electric company is well known.

The Joseph Dixon Crucible company of Jersey City, N. J., points out that it is the slipping belt that wears the leather. Belts that slip not only do not drive properly, but they wear out rapidly. A belt that is too tight is overstrained, and will also wear out rapidly. A thoroughly reliable belt dressing is therefore a necessity in every well-regulated factory, and perhaps no dressing has such a world-wide reputation as Dixon's belt dressing and leather preservative. As long ago as 1878 it was used on the big driving belt at the Paris Exposition, when every other means had failed to make the belt take hold of the pulley that was to start the thousands of feet of shafting and hundreds of machines. Those who use Dixon's belt dressing claim that it prevents slipping and thoroughly preserves the life and elasticity of the belt.

The electric-light plant now being placed in the new building of the Peruna Drug Manufacturing company at Columbus, Ohio, consists of two Ball engines of 160 horse power, built by the Ball Engine company, Erie, Pa., direct-connected to Siemens-Halske dynamos. The City of Erie is the name of a new passenger steamship building at Detroit for the Cleveland and Buffalo Transit company. This boat, which will be one of the most handsomely fitted on the great lakes, will have a large and complete direct-connected electric-light plant, consisting of Ball engines, built by the Ball Engine company, Erie, Pa., and dynamos built by the Fuller company of Detroit, Mich. The Shenango Valley Steel company, New Castle, Pa., is now installing a 450 horse power Ball engine, built by the Ball Engine company, Erie, Pa. The engines are belted to Westinghouse generators, and are used to generate power for electric cranes, electric lighting and kindred purposes.

Although many of the alternating-current stations have no day circuit and consequently have not thought it worth while to investigate the possibilities for revenue in the introduction of fan motors, yet it is on the hot and sultry evenings that the drug store, the soda-water fountain and the ice-cream parlor do their most thriving business. No matter how carefully these places are kept, as long as they have light it is impossible to prevent flies and other insects coming into the rooms unless the air is kept in motion. A ceiling fan motor, in addition to being an ornament, will not only keep the rooms free from flies and insects of all description, but will give a cooling breeze to the patrons of the places using them. The Western Electric company is agent in the West for the Tuerk alternating-current ceiling fan. This fan has been in operation for several years and has proved to be a satisfactory device both mechanically and electrically. All central-station men who are wide awake and looking around for means of increasing the revenue of their stations should investigate the merits of this fan.

The Mica Insulator company of New York, Chicago and London announces that it has recently made an addition to its already extensive line of oiled cloth and paper insulations, and is now prepared to furnish M-I-C compound, rope and bond paper. This line of insulation is made from the finest grade of rope and bond paper and treated with two baked coatings of M-I-C compound. The rope paper is furnished in sheets one yard wide, two yards long, and carefully packed between sheets of plain paper. The average breakdown test is 739 volts per mil; thickness, 4½ mils. The bond paper is furnished in sheets 19 by 24 inches and 22 by 34 inches, the average breakdown test being 859 volts per mil; thickness, five mils. The company will be pleased to send samples to electrical manufacturers, street railways or lighting stations upon application.

In addition to the contract recently secured from the city of Chicago, Sipe & Sigler of Cleveland, manufacturers of the Willard storage battery, report having delivered 58 cells to the Washburn Memorial Orphan Asylum, Minneapolis, Minn.; 64 cells to the Eclipse Electrical company, St. Louis, Mo.; 80 cells to the American Incandescent Lamp company, Warren, Ohio; 50 cells to M. A. Seed, St. Louis, Mo.; 28 cells to Prof. C. H. Wing, Ledger, N. C., and 38 cells to the Riker Electric Motor company, Brooklyn, N. Y. These batteries are to be used in connection with isolated plants. For telegraph and telephone purposes 100 cells were sold to the Home Telephone company, Cleveland, Ohio; 40 cells to the American District Telegraph company, Cleveland, Ohio, and several small orders to the Western Union Telegraph company. The horseless-carriage trade is brisk, and Sipe & Sigler have received within the last two weeks orders for 700 horseless-carriage cells, among the purchasers being the Riker Electric Motor company, Brooklyn, N. Y.; the United States Carriage company, Chicago, Ill.; the C. H. Barrows company, New York; Montgomery Ward & Co., Chicago, Ill., and the Gugler Electric company, Minneapolis, Minn.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued March 8, 1898.

600,134. Electric Locomotive. Harry Bitner, Chicago, Ill. Application filed June 19, 1896.

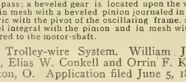
A frame is provided with a suitable motor for its propulsion, and a pair of supporting wheels, a shaft connecting the wheels, an oscillating frame carrying the shaft and provided with suitable pivots substantially in a line at right angles to the wheel shaft through the center of which they pass; a beveled gear is located upon the wheel-shaft and in mesh with a beveled pinion journaled in a line concentric with the pivot of the oscillating frame, and a gear-wheel integral with the pinion and in mesh with a pinion secured to the motor-shaft.

600,202. Trolley-wire System. William J. Kauffman, Elias W. Conkell and Orrin F. Kauffman, Canton, O. Application filed June 5, 1897.

Claim is made for the combination of a support or pole having attached thereto a bracket or arm, the pivoted bar carrying a trolley wire, the wire connected to the pivoted bar and to the switch-bar, the wire arranged as described, the switch-bar pivotally attached and located between the clips and the emergency wire.

600,228. Polyphase-current Transformer. Carl Kurda, Nuremburg, Germany. Application filed November 5, 1896.

A transformer for polyphase alternating currents consisting of two or more sets of inducing coils of different



NO. 600,134.

phase placed one upon another, in combination with laminated sheet inductive material surrounding the sets of inducing coils and separating them from each other.

600,230. Electro-therapeutic Exercising Apparatus. Abraham Martin, Paris, France. Application filed November 23, 1897. Patented in France May 10, 1897.

A system of electro mechanical apparatus for exercising the muscles of the human body and thereby generating an electric action applicable to all or any part of the body is described, comprising a frame, shaft, pulley actuating a magneto electric generator, whose poles are respectively connected to the hand grips of crank handle, a brake-drum encircled by brake shoes, segments embraced by a cord connected to a spring balance and also to a regulating pulley adjustable by means of a notched lever to vary the tension of the cord and spring-balance.

600,252. Means for Arresting Motion of Electric Cars. Wilbur C. Anderson, West Hoboken, N. J. Application filed August 30, 1895. Renewed October 2[illegible], 1897.

A local circuit including the motor or motors and the reversing switch or switches, two car controllers, two circuit closers or switches, one operated by each controller, the contacts on the controller and on the switches being so arranged that when the main source of current is cut off from the motors the switches are closed, completing the local circuit.

600,265. Electrical Measuring Instrument. Adrian H. Hoyt, Penacook, N. H. Application filed July 2, 1897.

The electric measuring instrument has a graduated scale and a pointer whose movement thereon is caused by the current on the circuit, suitable mechanism for preventing a return movement of the pointer to zero should the current be diminished or stopped after having recorded the maximum load on the circuit.

600,277. Electric Arc Lamp. James H. Duncan, San Francisco, Cal. Application filed July 13, 1897.

A fixed upper frame or base carries the actuating magnets, with upper carbon and clutch mechanism therefor, a lower movable frame normally upheld by a spring carrying the lower carbon and acting as a trip for the clutch mechanism and connections, whereby the lower movable frame is controlled by the actuating magnets.

600,278. Automatic Switch for Railways. Howard F. Eaton, Quincy, Mass. Application filed July 13, 1896.

A conductor and a traveling contact are combined with an operating magnet and a circuit-controller establishing the circuit of the operating magnet, the circuit-controller being arranged in series circuit with the conductor-operating magnet and traveling contact, and responsive to currents of a predetermined characterization only.

600,285. Electric Heater. Richard J. Holland, New York, N. Y. Application filed December 24, 1896.

The flexible, liquid-holding receptacle is provided with a contracted mouth or aperture, and there is an insulating closure consisting of a screw-plug having a connected housing, one or more resistance coils within the receptacle and attached to the screw-plug, electrical connections to the coil or coils within the housing, and a switch also within the housing, and by means of which the electric current may be turned off and on as desired.

600,336. Insulating Connector. Herbert E. Pearce, Brooklyn, N. Y. Application filed May 18, 1897.

An insulating connector for electrical fixtures has a top bracket formed with a hub, whose opening is larger than the diameter of the supporting pipe or rod, and set-screws in the hub for attaching the connector.

600,356. Automatic Regulator for Electric Currents. Joseph D. C. Chateau, Paris, France. Application filed July 10, 1897. Patented in France May 30, 1896.

An automatic regulator for electric currents is described, comprising a magnet or coil, an armature, a resistance, two contact pieces between which the armature is arranged, and connections whereby the coil, the armature, the resistance and one of the contact pieces are in the main circuit, while the other contact piece is in a shunt circuit.

600,380. Galvanic Apparatus. George H. A. Schaefer, Buffalo, N. Y. Application filed January 7, 1898.

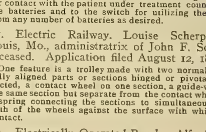
This apparatus consists of a cabinet having a lower compartment, an upper rear compartment and an upper front compartment, an angular cover for opening or closing the upper front compartment and a hinged side wall for opening and closing the lower and upper rear compartments, a number of batteries located in the lower and upper rear compartments, a series of metal plates located in the upper front compartment and successively connected to the batteries by negative wires, a series of positive wires successively connecting each battery with the next, a pivoted switch adapted for separate contact with the metallic plates connected to the batteries for increasing or lessening the electric current, and a positive and negative wire for contact with the patient under treatment connected to the batteries and to the switch for utilizing the current from any number of batteries as desired.

600,381. Electric Railway. Louise Scherpe, St. Louis, Mo., administratrix of John F. Scherpe, deceased. Application filed August 12, 1897.

One feature is a trolley made with two normally vertically aligned parts or sections hinged or pivotally connected, a contact wheel on one section, a guide-wheel on the same section but separate from the contact wheel, and a spring connecting the sections to simultaneously urge both of the wheels against the surface with which they contact.

600,383. Electrically Operated Brush. Alfred Sherwood, Topeka, Kan. Application filed March 1, 1897.

This is an electrical rotary brush, comprising the hanger having the integral arm and removable arm provided with handles, the motor having a frame whose tubular axis is fixed in the hanger-arm, the rotary motor-shaft passing through one end of the frame and having a pinion fixed thereon, the hollow brush proper inclosing the motor and



NO. 600,252

rotating on the frame portion and provided with the hub-gear, and the gear and pinion carried by hanger-arm and meshing respectively with the motor pinion and hub-gear.

600,417. Electric Heater. Edward E. Gold, New York, N. Y. Application filed August 12, 1897.

An electric heater comprising a helix of resistant wire coiled into a compound helix is combined with a support therefor, the helix being compressed against the support so that it exerts an expansive tendency.

600,457. Electrical Battery. Nathan B. Stubblefield, Murray, Ky. Application filed October 24, 1896.

A combined electrical battery and electro-magnet for use with water as an electrolyte, comprising a soft-iron core-piece and a voltaic couple of copper and iron wires insulated from each other and closely and compactly wound together in separate insulated layers to produce a solid coil body surrounding the soft-iron core-piece.

600,475. Electrical Insulator and Method of Making Same. John W. Boch, East Liverpool, O. Application filed October 23, 1897.

A porcelain or earthenware insulator is made of two or more parts fitted one within the other, with extra glaze introduced to fill all the spaces where the parts are to be united, and forming an intermediate solid layer or layers of glaze between the conductor and pin.

Western Electrician.

EVERY SATURDAY.

Vol. XXII. CHICAGO, MARCH 26, 1898. No. 13

Ice-bridge Formation at Niagara.

By Orrin E. Dunlap.

This year Niagara Falls has been treated to the rare spectacle of an ice bridge in March. It is the time of year that makes the formation most interesting, for Niagara ice bridges are usually the product of a thaw in the early days of January. Old residents at the Falls have come to look upon the first 15 days of the year as the ice-bridge time, and when the middle of the month goes by without a bridge forming they give up hope for the season. Ice bridges have formed at Niagara later than March, but their existence was brief, say a portion of a day or night. This year's bridge formed on the night of March 13th, and when the people awoke on the following morning they were surprised to learn of the existence of a bridge, ample in size and beautiful in outline. Its formation was just two months late, but despite this fact it was none the less welcome.

The views presented on this page illustrate this bridge as it was seen from the Gorge road. The pictures give a faithful idea of where the ice bridges form (Fig. 1), many pictures failing to do this. It will be seen that its location it at the foot of the falls, where the water is nearly 200 feet deep and the current is very rapid. People crossed back and forth on the icy mass, but the travel was not so great as in some previous years. The incline railways in the free parks on both sides of the river afforded easy access to the ice jam, and saved long walks up the stairways.

The other winter views presented show the Gorge road under snow. Fig. 2 is a view of the cut through which the road descends to the slope leading to the great bridges and rapids. Fig. 3 pictures the slope and view as seen in winter, while Fig. 4 looks still farther toward the rapids and shows the great new steel-arch bridge as it appears to-day, when viewed from the Gorge road.

In summer the Niagara gorge is beautiful from end to end, but under a heavy fall of snow its attractiveness is wonderfully increased, and it is admired by many who visit Niagara in the winter.

ICE-BRIDGE FORMATION AT NIAGARA.

Electrical Men Suffer Loss in a Chicago Fire.

Of several disastrous downtown fires in Chicago within the last week or so, the one that destroyed the Schoeneman building on Monday, although not marked by the distressing loss of life of some of the others, is of particular interest to the electrical fraternity, from the fact that a number of electrical men were among the tenants. The building was seven stories high and located at 303 and 305 Dearborn street, in the heart of the "electrical district." It was provided with power and the upper floors were rented to small manufacturing concerns. The fire started shortly after noon, and the building and contents were entirely ruined. The origin of the fire is not definitely known, but there appears to be no basis for the statement in some of the daily papers that it was caused by an electrical short-circuit.

Sargent & Lundy, the electrical engineers, had a storeroom in the basement, in which was a stock of 11 C. & C. motors, ranging from one-half to 10 horse-power, and 6,000 incandescent lamps. The apparatus was valued at $2,500, and it is feared that it is nearly a total loss. The insurance is $2,000.

On the second floor the Lovell Storage Battery company had its office and plant. This company manufactures bicycle and carriage lamps and physicians' electrical outfits. It lost everything except the papers in the safe, which, it is hoped, may be found uninjured when the debris is overhauled.

Mr. C. E. Lee is in England at the present time on business connected with the company, and the establishment was in charge of Mr. L. W. Collins, who says that the business will undoubtedly be resumed in a few days. The loss is placed at $1,500, to offset which there is insurance amounting to $1,000.

About six weeks ago the newly organized Rae Motocycle company established a workshop on the second floor of the building for the manufacture of storage batteries for vehicles, and it has lost property valued at about $500, with no insurance. A quantity of the personal effects of Frank B. Rae, the vice-president of this company, was stored in the shop and was destroyed. Mr. Rae is of an inventive turn of mind, and his belongings consisted of three-phase experimental apparatus, a complete electrical cooking outfit, elevator-starting mechanisms, electrical designs and other paraphernalia of an electrical inventor. Much of the apparatus cannot be replaced easily, and it is difficult to place a valuation on the collection, but it was probably worth $2,000 at least. Mr. Rae had no insurance on this property. He was out of town at the time of the fire. This is not Mr. Rae's first experience with fire, as his Detroit shops were burned out about five years ago. The business of the Rae Motocycle company will not be seriously interrupted.

H. C. Porter, a storage-battery manufacturer, was engaged in the laboratory of the Rae Motocycle company and sustained a personal loss of $250, without insurance.

Thomas Wrigley, a machinist, who made toggle bolts and other appliances for electrical use, had a shop on the seventh floor. He lost all his tools, patterns and machinery, valued at about $2,000. It is said that Mr. Wrigley had no insurance.

Otto Pfau, an arc-lamp maker, had lately moved into the building, and he lost a small outfit.

Distortion Measurements in Sciagraphy.

By O. L. Schmidt, M. D., and W. C. Fuchs, E. E.

All experimenters with the X-rays observed very soon that a certain distortion of the shadow occurs whether it is observed by the fluoroscope or by the sciagraph; in fact, the fluoroscope shows this more plainly than the sciagraph, as by shifting the position of the tube, the fluoroscope or the observed object, strange distortions of the shadow on the screen can be produced at will and seen changing from degree to degree. When the object and fluoroscope are fixed, a displacement of the Crookes tube in any direction in space produces a change in the shadow.

When the tube is moved laterally the distortion is most evident on the opposite side of the shadow, and when the tube is shifted nearer or farther away from the object the shadow also changes. It becomes larger or smaller in inverse proportion to the distance of the tube, while the focus area remains stationary. It is evident that in sciagraphy the object is placed as close as possible to the sensitized plate, and that the center of the picture is put into the focus point either because this is the part we wish to examine most carefully or because the picture is large, so that we wish the periphery to have the unavoidable distortion equal at all points, thus giving symmetrical errors and allowing comparisons with the least possible erroneous deductions.

The object of our experimentation was to determine limits of this variation for practical purposes, so that we might give approximate information on distortion in sciagraphs where the distance of the tube and the thickness of the object are known. For accurate localization the instruments known as fluorometers have been introduced. The object is exposed to the rays in different positions and the shadow taken on the fluoroscope or the plate with the fluorometer adjusted according to the focus point. By triangulation the position of the object may then be computed.

To determine the focus point various methods have been introduced; these are constructed on the principle of bringing the tallic rods on a line into the strongest area of X-rays, so that but one shadow appears on the fluoroscope or sciagraph. We use a simple focus tube of the following dimensions: Lenght, 11 inches; diameter, four inches; distance between electrodes, six inches.

A distance of five centimeters from the anode to the plate has seemed to us suitable for most tubes. A test-box was constructed so that a series of brass rods, separated two centimeters from each other, could be arranged on level of 2, 4, 6, 8, 10 and 12 centimeters above the sensitized plates. Sciagraphs were then taken of these rods at the different levels. The center rod was always put into the exact focus point by the principle mentioned. That this can be done very accurately by the fluoroscope was shown on the sciagraphs, where only one clear shadow is visible on the focus line. By measuring the distances between the shadows on the plates, it was found that they varied uniformly according to the distance of the rods from the focus line and their distance from the plate.

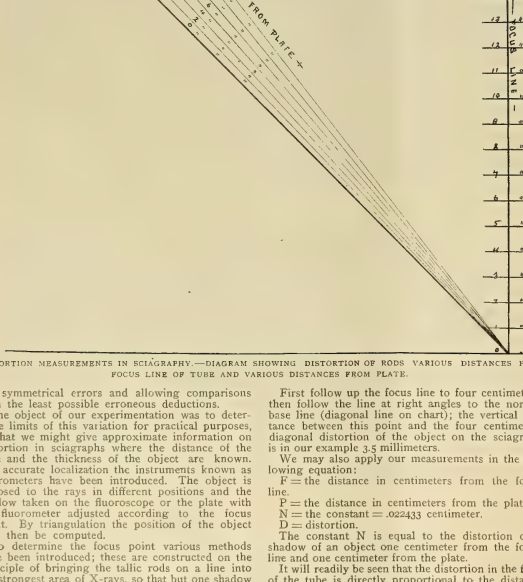
The results of the measurements of the different plates agreed so perfectly in their proper comparison with one another, that the accurate mean of these figures was easily obtained.

The sciagraph shows: First, the distortion is directly as the distance of the rods from the focus line; secondly, the distortion is directly as the distance of the rods from the focus plate.

From these priciples and the actual measurements, we have constructed a graphic method in the form of a curve, so as to readily determine the possible distortion of a shadow on the sciagraph. This is shown in the accompanying illustration.

The figures on the vertical line in the center indicate the distance from the focus line. The heavy diagonal line represents the sciagraph of the rods while placed on the plate, so that no distortion occurred. Above this heavy diagonal line there are diagonal lines marked in centimeters, to denote the distance of the rods from the plate; they represent by their distance from the normal base line the distance of the shadow.

Example: What distortion will an object have four centimeters from the focus line and four centimeters from the plate?



DISTORTION MEASUREMENTS IN SCIAGRAPHY.—DIAGRAM SHOWING DISTORTION OF RODS VARIOUS DISTANCES FROM FOCUS LINE OF TUBE AND VARIOUS DISTANCES FROM PLATE.

First follow up the focus line to four centimeters, then follow the line at right angles to the normal base line (diagonal line on chart); the vertical distance between this point and the four centimeters diagonal distortion of the object on the sciagraph is in our example 3.5 millimeters.

We may also apply our measurements in the following equation:

F = the distance in centimeters from the focus line.

P = the distance in centimeters from the plate.

N = the constant = .022433 cetimeter.

D = distortion.

The constant N is equal to the distortion of a shadow of an object one centimeter from the focus line and one centimeter from the plate.

It will readily be seen that the distortion in the field of the tube is directly proportional to the distance from the focus line and also the distance from the plate.

Example: What will be the distortion of an object eight centimeters from the focus line and 10 centimeters from the plate?

D=.022433×10×8.

D=1.79464 centimeters.

Thus we have a ready method of estimating the probable distortion on a sciagraph of an object of unknown position, in a body of known thickness where the focus line has been determined, and the distance of the tube from the plate is 50 centimeters.

B. W. Dinsmore has franchise for lighting the city of Marion, Va., and will erect plant of 400 incandescent lights of 16 candle power each.

Direct-coupled Set.

A direct-coupled engine and dynamo now on the European market which has been designated the Mertz-Alioth is shown in Fig. 1 (page 181), reproduced from l'Industrie Electrique. The advantages claimed for the combination are a compound engine coupled to a small dynamo, all of such reduced dimensions as to permit its use in very restricted quarters. The total length of the combination is two meters and the height of the engine one meter. The dynamo is .6 of a meter high, and the respective widths of the two are .8 and .6 meter. The total weight of this machine is 1,740 kilogrammes, and it is rated at nine horse power.

The engine is compound, has an effective steam pressure of eight kilogrammes per square centimeter, with one high and one low-pressure cylinder, whose diameters are respectively 170 and 260 millimeters. The two pistons, mounted on the same crank-shaft, give 520 revolutions per minute, and by the peculiar arrangement of the cranks and a cushioning of steam in the cylinder the trepidation and shock is completely overcome and the motion is uniform under all loads. The principal moving parts, as shown in the sectional view, Fig. 2, are all concealed, which permits of liberal oiling of the cylinders, while some other portions of the machinery are supplied by a pump, actuated by the machine itself. The regulator is of the centrifugal pattern, which governs the admission of steam into the steam chest, whence it passes into the cylinders, and this, being also inclosed, is lubricated in the manner already described. A heavy balance wheel, shown in the cut, aids in regulating the action of the engine and dynamo.

The dynamo coupling is screwed directly on the face of the balance wheel. This generator delivers a continuous current of 125 volts tension, and its industrial efficiency is 88 per cent. Its magnetic field, formed of four poles, is fed by four spools connected in pairs upon two derivations from the brushes. The air space is four millimeters. The cylinder has a diameter of 248 millimeters and the opening between the jaws of the magnets is 252 millimeters. The speed of the revolving portions is 675 meters per second.

It will be noticed that the combination throughout closely follows American apparatus that has long been on the market.

Central Power Plants on Board Ship vs. Distribution of Power.[1]

By William S. Aldrich.

There are certain inherent advantages in centralizing the generation of power for any given purpose. In almost all cases the original sources of power for the purposes under consideration are the steam engine and boiler plants. In all cases of the use of steam it has been long known and practiced, as well in its generation as in its utilization, that greater economy is to be effected by a centrally located plant. However, when it relates to the transmission and distribution of power from such central steam plant as are at once confronted with the claims of three principal rivals, namely, compressed air, water pressure, electricity. In particular, on board ship, we believe there will be reduced cost of installation, increased economy of operation, fewer men required in operation and management, if all the power required for the several auxiliaries should be developed in a single power plant. The same principle has been fully worked out in the mechanical equipment of modern office buildings, hospitals and other public institutions, department stores and isolated plants.

Only one working fluid is actually required for all cases of power distribution. If we are permitted for a moment to speak of electricity after the manner of the old school and to consider it as a working fluid, then it is quite clear that all of the auxiliary machinery on board a naval vessel may be operated by any one of the working fluids—steam direct from the boilers, compressed air, water pressure or electricity. Moreover, only one working fluid is actually required.

All the various operations now carried on by so-called "mixed systems" of power distribution on board ship can be effectively reproduced and satisfactorily performed by suitable motors and mechanisms driven by any one of the working fluids already mentioned. Primarily, of course all power for such distribution is to be derived from steam engines. Therefore the efficiencies of transformation of energy in each of the above cases should not be left out of consideration. It is not our present purpose to enter the discussion respecting such efficiencies of transformation involved in converting steam power into compressed air, water pressure or electricity.

For all the purposes, therefore, for which power may be required on board ship it may be developed:

(1) In a centrally located plant. This should, of course, be as near the battery of boilers and main engines as possible, placed in the same or adjoinwater tight compartments, and all below the protective deck.

(2) At points where the power is to be utilized. In this case several power-generating plants require to be located in different parts of the ship, being

1. Journal of the American Society of Naval Engineers.

most suitably installed at or near the centers of distribution. In this case, however, it must be remembered that steam from the boilers is the original source of energy for the distributive development of power. All prime movers for any system of power generation on board ship are and will continue for a while to be of the various types of simple and compound steam engines.

Should the power required at any point be developed elsewhere in a central plant and transmitted to that point for direct utilization? Or should such power be generated by a steam engine on the spot and further transformed into compressed air, water pressure or electricity, as may be required for application at such point? It will be seen that the whole problem resolves itself largely into a question of the distribution of power. The distances for such distribution are so short on board ship that there is practically no necessity for considering any of the so-called line losses in power-transmission work. The transformation losses, however, are vitally important. In any case these should not exceed, if they should ever be found to equal, the present losses from mechanical friction alone in the many auxiliary steam engines scattered throughout the ship. Losses incident to the transformation of energy vary slightly with the load, but in a different manner for each of the working fluids noted. Again, such losses, if confined to a central-power plant, should not even approach those of similar losses in the transformation of energy in the different power-generating steam engines scattered throughout the ship. The question of the storage of energy is not so important on shipboard as might, on first sight, appear. Compressed air probably admits of the readiest storage for use on naval vessels, with the least disastrous results from shot and shell. A storage battery for electricity or a hydraulic accumulator are practically out of the question. The former requires no system of storage for use on shipboard; the latter almost imperatively requires such storage for maintained distribution of energy.

Looking for a moment at the steam engine required for such a central-power plant, it will be found to be advantageous to subdivide the plant into generating units. Representative types of compound engines now so extensively used for such subdivision are chiefly of the self-contained type. There would be little use for single or paired simple engines for such a central plant.

If steam power is converted into electricity for all of the operations required on board ship, it will be interesting to note different characteristic features of such installation. It would be beyond the range of the present paper to investigate fully the

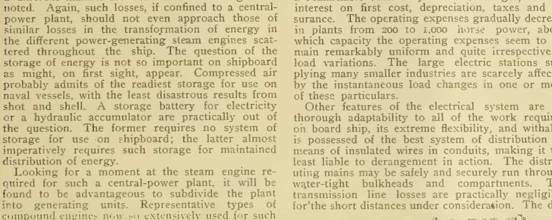


FIG. 1. DIRECT COUPLED SET—MERTZ-ALBOTH COMBINED ENGINE AND DYNAMO

comparative advantages and disadvantages of each of the systems of power distribution—steam, compressed air, water pressure and electricity. The present purpose is merely to have in hand some definite system for a discussion of the steam generating plant required, should all of the power be thus developed in a central plant.

Consider a central power plant made up of compound condensing steam-engine units, each a duplicate of the other, with all parts of the same size and respectively interchangeable, and certain advantages will at once be apparent, namely, the plant may be operated at all times in such a manner that each engine is loaded to its full normal capacity, variation in load may be met by throwing in or out one or more of such steam-engine units. The range of power for variation of load will in no case be imposed on any one engine as in the several steam engines used to drive the scattered auxiliaries.

In the matter of equalizing the load on such a power plant driven by duplicate steam-engine units, it is seen that the conditions are ideal and extremely favorable when applied to electric generation. The plant may be operated at a nearly uniform load day and night, respectively. The electric light load at night may be offset by additional electric-motor load during the activities of the day. Also, certain pumping machinery can be operated at any time by electric motors during the day or the night, so that these may be thrown in or out to compensate for otherwise large variations in load. One in charge of such a central electric-power and lighting plant on board ship would be able to so operate it and obtain a load curve which would be the admiration and envy of central-station managers on shore. Station indicators would so indicate terminal conditions on the circuits that the most efficient operation of the plant would be obtained at all times.

It is quite impossible to treat of this question without further treading upon the debatable ground respecting the merits and demerits of the different methods of power distribution. In all cases, however, the following economic features should be carefully weighed for any given or specified service: Cost of installation, running expenses, involving pay of attendance, cost of coal and water, oil and waste, depreciation and repairs.

In this connection it is important to notice the results of H. A. Foster's analysis of the tests of 22 different power plants.[1] These included manufacturing establishments, electric-light stations, pumping engines, etc. Plants above 200 horse power show a remarkable uniformity in fixed charges, namely, interest on first cost, depreciation, taxes and insurance. The operating expenses gradually decrease in plants from 200 to 1,000 horse power, above which capacity the operating expenses seem to remain remarkably uniform and quite irrespective of load variations. The large electric stations supplying many smaller industries are scarcely affected by the instantaneous load changes in one or more of these particulars.

Other features of the electrical system are its thorough adaptability to all of the work required on board ship, its extreme flexibility, and withal it is possessed of the best system of distribution by means of insulated wires in conduits, making it the least liable to derangement in action. The distributing mains may be safely and securely run through water-tight bulkheads and compartments. The transmission line losses are practically negligible for the short distances under consideration. The distribution losses on the several branch circuits alone require detailed consideration. The direct current is, of course, to be used in all cases. In such a system it is possible to secure a higher maintained efficiency of operation of the plant than any other system, and this is really the point to be desired in any such installation. In the electric system, also, it is possible to control with known certainty distant motors for various auxiliaries, and such control may be from one central point.

The electric system alone admits of such subdivision of the generating plant into equal and interchangeable engine-dynamo units. The advantages of this on shipboard are too apparent to require discussion.

There is not now an auxiliary on board ship which cannot be operated with certainty, efficiency and economy by electric motors. All pumps, fans, blowers, hoists, lifting and steering gear, turret gear and gun mounts may be so operated, and are every day reaching toward this system of operation. The same may be said of the air compressors required for refrigerating purposes.

Boiler-feed pumps can now be far more economically driven by electric motors than by any of the present types of steam-engine cylinders usually attached to the same. They may be set at any time for various rates of feed, and with certainty, from a switch in the boiler room. Air pumps and condensers may be similarly operated, and have their speed and vacuum controlled by a simple switch in the engine room. All low-lift suction pumps, bilge pumps, etc., may be very efficiently operated by either geared or direct-connected, slow-speed electric motors. In fact, the whole of such electric lighting and power-plant installation on board ship may be operated at all times at the most economical and nearly uniform loads, and at uniform steam pressures and speeds for the dynamo engines. This cannot be said of the steam engines operating any other kind of auxiliary machinery or operating any

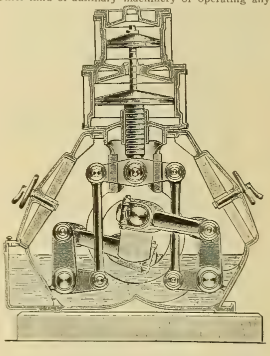

FIG. 2. DIRECT-COUPLED SET.—SECTIONAL VIEW OF ENGINE

other system of power distribution. The inherent advantages of the electric system are chiefly due to the facility of transformation of electrical energy, especially in view of the fact that all such transformations (with or without load variations) in no special manner affect the efficiency and economy of the steam engines driving the electrical generators.

Concerning the effect of variations of load in modern electric-power-plant engines, it is interesting to note that A. G. Pierce and R. S. Hale state of the Boston Edison stations: "As a matter of fact, the steam per indicated horse power in our two 200 units holds within 12 per cent. over a range from one quarter up to full output."[2]

While the above has been noted in the case of large engine-dynamo units, it is none the less true that remarkably uniform rates of steam consumption may be obtained in smaller compound direct-connected units, as has recently been noted in the journal of our society. Two questions are primarily involved in a general consideration of this problem: Economy of installation and efficiency of operation. Respecting the first, it is possible to obtain refinements of design and economic arrangements of installation not yet reached in electric power plant by adopting heat unit specifications and subsequent contract trials upon this basis. At least, the efficiencies, economies, guarantees and contracts now being realized in modern high duty pumping plants should be much more nearly approached in electric power plants. The special features of such heat unit ratings have been presented by the author in two recent papers before the American Society of Mechanical Engineers, from which, Table I. on page 182 has been taken, being compiled from the report of the committee on data of the National Electric Light association, Buffalo, June 8, 1897.

The writer further pointed out in the above paper that some very uneconomical engines have produced remarkable results in point of economy of operation and efficiency of installation. The best of engines may be poorly operated on the one hand, and the whole plant badly arranged on the other.

We enter as strong a plea as anyone for the most economical engine for electric power plants, but we wish to add a further requirement that there should be economic installation and efficient operation to produce the best all round results in the

course of a day, a month or a year. Should the government require heat-unit specifications and contract trials for the electric-light and power plants installed on board naval vessels, much better results would be shown than those heretofore attained, of which the performance of the dynamo engines of the U. S. S. Minneapolis, as reported in another paper at this meeting of the society, may be taken as a fair example. In this case there are three duplicate sets of electric-generating units. Each set is driven by a pair of simple engines, 10½ inches diameter, five inch stroke, at speeds ranging from 382 to 425 revolutions per minute, and developing from 17 to 35 indicated horse power under normal working range of loads. Under the best conditions reported (when these engines were tested after several days' run with new pistons and packing rings), the steam consumption ranged from 56 to 88 pounds per indicated horse power per hour. Similar tests have been previous required, it is true, but the contract trial has

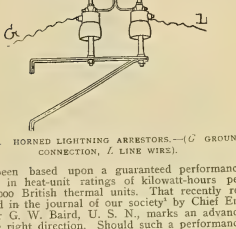

FIG. 1. HORNED LIGHTNING ARRESTORS.—(*G* GROUND CONNECTION, *L* LINE WIRE).

not been based upon a guaranteed performance stated in heat-unit ratings of kilowatt-hours per 1,000,000 British thermal units. That recently reported in the journal of our society[1] by Chief Engineer G. W. Baird, U. S. N., marks an advance in the right direction. Should such a performance of electric-power plants be determined in accordance with and based upon ratings on the B. T. U. standard, it would be of great value for establishing engineering precedent in reference to the power required by the auxiliary machinery driven by electric motors.

As a further example of the values to be obtained when rating the performance of an electric-power plant on the heat-unit standard, Table II. has been prepared.

TABLE II.

Performance of the electric-lighting plant of the Government Hospital for the Insane, at Washington, D. C., based on the heat-unit standard, from results reported by Chief Engineer George W. Baird, U. S. N.

	Small plant.	Large plant.
Date of making test	Nov. 19, 1896.	Dec 1, 1896.
Number of kilowatts per hour	37.20	108 90
Pounds of feed water pumped into the boilers per hour	2,285 00	4,481.50
Mean temperature of feed water, in degrees Fahrenheit	129 9	125 9
Steam pressure in boilers, in pounds per square inch above atmosphere	93.41	92.33
Total heat in one pound of steam, being the heat required to raise one pound of feed water from its temperature to that of the steam at the boiler pressure and evaporate it into steam at that temperature (Kent's tables)	1,085.7	1,089.5
Plant rating—		
(1) Kilowatt hours per 1,000 pounds of feed water	25 03	24.30
(2) Kilowatt hours per 1,000,000 British thermal units supplied to the system	23.06	22.30
Engines, cross-compound, rope-belted to dynamos. Diameters, inches	10½ and 16½	13 and 20½
Stroke, inches	12	12
Indicated horse power developed, when loaded	103.64	197.07

Wherever power is to be transmitted or energy distributed, even for such short distances as occur on board ship, and in varying quantities for many different sized units, the most expensive of all methods is that by the use of steam as the working fluid. While it has been found in many cases desirable, for some purposes, to have a combination or mixed system for distributing power from a central station on board ship, it can scarcely be said to be in accordance with the best engineering practice.

For all operations involving rotary motion, continuous or intermittent, uniform or variable unidirectional or reversible, electricity stands pre-eminently at the head. For certain very definite reciprocating movements with fixed time or distance limits, hydraulic mechanism or electric motor-driven mechanism with hydraulic control, has proven best suited. For reciprocating movements require a cushioning effect, compressed air is better adapted. For efficient service in any case, however, compressed air requires to be reheated and used expansively in a cylinder with all parts and mechanisms practically the same as in the steam engine.

No one system of power transmission can well be

[1] "The Construction, Installation and Performance of the Electric Lighting Plant of the Government Hospital for the Insane, at Washington, D. C." Journal of the American Society of Naval Engineers, Vol IX., No. 2, p. 391.

advocated from a central station until a thorough trial has been made of one system throughout any given ship. This has been pointed out by George W. Dickie, in a recent paper before the American Society of Mechanical Engineers, on "Auxiliary Engines and Transmission of Power on Naval Vessels."[1] Mr. Dickie states: "In the present state of the art of transmitting power to all parts of the modern warship, it is not possible to compare one method with another as a whole, and from actual experience, there being no one ship with a complete system of transmission from a central generating station of one type to compare with another ship having an equally complete system from a central generating station of another type."

There are certain inherent considerations in the use of any working fluid, as well as practical details for its distribution, which set the limits for each of the respective systems. Steam, electricity and compressed air will stand up to the work and permit a considerable overloading of generators and motors. The hydraulic system, on the other hand, is limited and must be installed throughout large enough for the maximum capacity ever likely to be required of it. Again, it is clearly of little avail to transmit power by water or compressed air and have to transform it again into any particular mechanical movement or any required source of energy whenever and wherever such may be required on board ship. Light, heat, ventilation, power for rotary and reciprocating movements, water for sanitation and fire service, and refrigeration are all required to be amply provided for, and such services efficiently maintained on board every naval vessel. That merchantmen have led the way in some instances in the application of electrical distribution for several of the requirements above noted may serve to indicate the possibilities in store for similar central electric-light and power plants to be located on naval vessels. Electricity may, directly or indirectly, provide for all of the above services on shipboard and in an economical manner, with the exception of distributing heat. This, of course, will remain to be supplied by steam distribution or the forced circulation and ventilation of the hot-air system. For quickness and certainty of action as well as almost instantaneous application of the motive power applied, electricity scarcely has a competitor, especially when the power is to be applied in an accumulative manner. An example of this is the recent contract for the operation of the turrets of the battleships Alabama and Illinois by electric motors, following in the wake of the cruiser Brooklyn, similarly fitted out with electric gear.

[1] Transactions of the American Society of Mechanical Engineers, Vol. XIX., No. 761.

Horned Lightning Arresters.

At a recent meeting of the French Society of Civil Engineers, M. V. Langlois mentioned particularly some peculiarities of an installation for the transmission of energy made by Siemens & Halske of Berlin, and Lahmeyer, from which the facts are taken, says that the power station is at Tervueren, while the receiving station is at Brussells. The conductors of this aerial line are three in number and of copper. The tension at the generator, 4,000 volts, is reduced to 120 at the receiving terminal by two tri-phase transformers.

Very thorough precautions have been taken in the installation, not only in perfect construction, but in the highest possible insulation. All the insulators are the triple-petticoat form, of porcelain. The posts supporting the insulators are about eight meters high, and placed at distances of 40 meters. The total loss in the line is about 7.2 per cent. Guard wires, connected to earth, are placed at all crossings to prevent accident in case of a break in the line.

The lightning arresters, called "horned arresters," distributed along the line, are very interesting. They are made up of two copper wires, sufficiently strong, recurved in the same plane, facing one another, in the form of horns, as shown in Fig. 1. These are fixed on porcelain insulators. One of these, G, is in contact with the line—the other, L, leads directly to the earth.

If the lightning strikes the wire it finds a path to the earth by crossing the minute film of air between the horns. An arc is at once formed at this point; the heat makes an upward current in the air, which rises until the arc is broken—blown out. Fig. 2 represents the appearance of such an arc, resulting from a short-circuiting of 10,000 volts.

One of these arresters is placed on each of the three wires at the entrance of each terminal station and at three intermediate points on the line. In addition to these arresters, each wire is furnished with a cut-out, composed of fine copper wires in glass tubes filled with gypsum. An overplus of current in the primary fuses these wires and opens the circuit.

TABLE I.

Showing examples of rating electric power plants on the heat-unit standard, reduced from 1897 report of committee on data of National Electric Light association.

Station No. in 1897 Report N. E. L. A.	Pounds feed water per kilowatt-hour at best efficiency.	Temperature of feed water, Fahrenheit.	Steam pressure above atmosphere, pounds per square inch.	Total heat B. T. U. in feed water per pound.	Plant Ratings. Kilowatt-hours per 1,000 lbs. feed water, gross efficiency.	Kilowatt-hours per 1,000,000 B. T. U. at best efficiency.	Type of engines.	Rating at best efficiency, water per I. H. P. hour.	Method of driving dynamos.	Dynamos daily output. Watt-hours.	Kind of service daily.

Philadelphia Electrical Exhibition.

The Philadelphia Electrical Exposition company will give an electrical exhibition in its building 818 and 820 Chestnut street, beginning June 6th, and continuing for one month. There has been no exhibition given in that city since 1884, and it is believed public interest will be aroused by a systematized attempt to show the progress of elec-

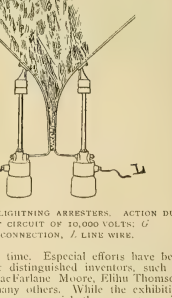

FIG. 2. HORNED LIGHTNING ARRESTERS. ACTION DURING A SHORT CIRCUIT OF 10,000 VOLTS; *G* GROUND CONNECTION, *L* LINE WIRE.

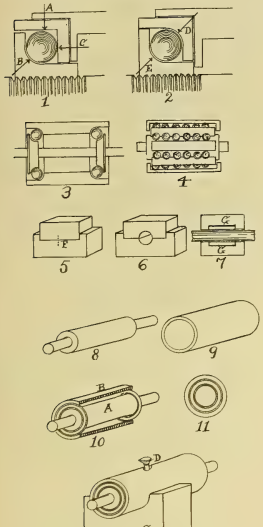
tricity since that time. Especial efforts have been made to interest distinguished inventors, such as Edison, Tesla, MacFarlane Moore, Elihu Thomson, Steinmetz and many others. While the exhibition will necessarily be commercial, the promoters give assurance that no pains will be spared to make it of the highest scientific character. Much thought and time will be given to tasteful decorations, and good music will be a feature. The management has obtained the services of Prof. William D. Marks as director. His former experience as manager of the Franklin Institute exhibition and his intimate knowledge of the advances in electricity qualify him for this new responsibility.

Bearings in Electrical Machinery.

By B. F. Fells.

Owing to the high speed at which most electrical machinery is run, the bearings are a potent factor. Forms of ball bearings are useful to builders of certain kinds of electrical apparatus. Again, we find types of aluminum and even glass-bushed bearings. In one style of ball bearings there are but four balls on each cone, and these are kept in position by a ring, which is provided with a socket for each ball. The cone is held to the shaft with a key. A variety of forms for cones and ball-retaining casings is in use. The pattern in Fig. 1 is a three-point bearing, the ball contacting with the cone at B and the case at A and C. It is a good form of bearing and useful in many places on electrical machinery journals, providing that the balls, cones and cups are absolutely true, smooth and non-elastic. Each ball should be tested and found strong enough to carry alone all the weight which may be put on the bearing, because it is at times called upon to take practically all of the load for an instant.

Some builders of electrical machinery use the two-



BEARINGS IN ELECTRICAL MACHINERY.

point bearing, shown in Fig. 2, in which the ball contacts with the cone at E and with the case or cup at D. In some of the first patterns of ball bearings a flat rolling surface was provided for the balls. It was found that the balls were free to become displaced laterally, and to overcome this the surfaces of the cone and cup are now made concave, as shown. In another style the balls are linked by a shaft and kept in place by the casing. One might suppose that the balls would groove the shaft. The arrangement results in a two-point contact for the top series of balls and a three-point contact for the lower, as the latter touch the lip on the casing.

The pattern in Fig. 3 is fitted with cones of large diameter, and is applicable for high speed.

Roller and Ball Bearings.

In the combination roller and ball-bearing design in Fig. 4, it is apparent that the adjacent surfaces of the balls and rolls rotate in opposite directions, yet there is practically no friction between them, because there is no positive pressure of one against the other. This kind is used for bearings which must run very steady.

Wood Bearings.

There are times, when it is necessary to make a bearing of wood. Select good, clear stock and cut out the body pieces and start a guide for the auger by sawing into the top and bottom, straight across, as at F, Fig. 5. Then bore for the shaft, as in Fig. 6. Fig. 7 shows a section with the stock cut out at G G, into which space some bushing may be placed. Bore a hole at each corner for the bolts.

Process of Making Aluminum Bearings.

A good alloy from which to make bearing sleeves for electrical machinery is made as follows:

Aluminum	94.10
Antimony	4.01
Tin	0.88
Copper	1.01
Total	100.00

The tensile strength of sleeves made from this alloy is 24,000 pounds.

Glass Bearings.

Traulinie gives the tensile strength of glass at from 2,500 to 9,000 pounds per square inch, according to variety; crushing strength, 6,000 to 10,000 pounds per square inch. Transversely, flooring glass, one inch square and one foot between the end supports, breaks under a certain load of about 170 pounds. The glass is bought at glassworks and molded into bushings for journals. It has been used with some success on light work.

Making Bearings and Journals.

To cast sleeves for journals, secure a mandrel (Fig. 8) of the same size as the shaft and steel. Fit over this a steel case (Fig. 9). The sectional view in Fig. 10 shows the case B on the mandrel with the collars (a a) between. A cross-section is given in Fig. 11. The device, set up and ready for pouring, is shown in Fig. 12. The anvil is marked C and the pouring funnel D. In order to compensate for contraction a piece of paper may be wrapped around the shaft and wound with a thread. Clean away dirt, oil, etc., before pouring. It is a good plan to warm the mandrel before pouring; this will prevent chilling and blocking up the passage.

Trueness of Bearings.

Electrical machinery bearings must be perfectly true to avoid heating from the high speed often required. The tendency is for some bearings to contract at point E, Fig 13. Others fail to adjust correctly, as at F, Fig. 14. Again, the sleeves do not join, as shown at G, Fig. 15. Turning out on the lathe and sometimes filing will remedy the evils.

For testing the friction of a bearing which is supposed to be untrue, fix a small grooved pulley to the shaft of the bearing. A cord is then wound about the pulley and run down a scale. The bottom of the latter should bear weights. Whatever weight is required to start the bearing to turning and keep it going will be recorded on the scale, and the proportion of friction, etc., may be determined by the use of the tables given in engineering books.

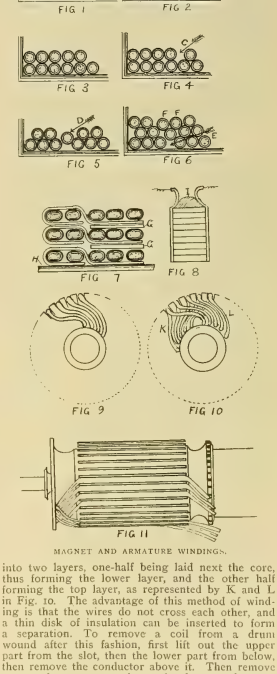
Magnet and Armature Windings.

A contributor of the Western Electrician, who sends the accompanying drawing, notes a difficulty which always presents itself when winding magnet coils and which is shown at A (Fig. 1). The wire is wound on the plan of a screw thread, necessarily, and the space for the last round is narrowed down too much for the coil to fit. There are many men who make a business of winding magnet coils who overcome this trouble by forcing the last turn down, crowding the coils, and oftentimes injuring the yielding insulation to such a degree that its efficiency is affected. This is carried to such an extent at times that the insulation is badly cut between the wedge-like edges. On the other hand, if the last coil is not pressed down into place and the second layer is wound, as in Fig. 2, a space will exist at B. These places form the base of that evil known as spreading. As is known, the least spread of the wires in the lower layer produces serious undulations in the successive layers, for the depression in the layers increase towards the surface. If the coils are wound as in Fig. 3, one layer topping the other, winding right-hand for first layer and left-hand for second layer, it is found that the last layer is gaining on the first, with the result that one is obliged to allow the wire to drop over between the wires ahead, thus leaving a space at C (Fig. 4).

The consequence of continuing to wind after the misplacement of one or more coils is illustrated in Figs. 5 and 6. If a second-layer wire takes the position shown at D (Fig. 5), and winding is continued over this, we get something after the plan in Fig. 6, in which E shows the space left in the first layer and F F the two wires of the third layer sunk below the proper level, owing to the dropping of the wire of the second layer into the space E. Two ways are employed to overcome these troubles. One is the result of long practice with winding magnet coils, which qualifies one to calculate closely on the required compactness of the layers to keep each even. The other method calls for figure work. The size of wire to be used is calculated, the insulation allowed for, and the number of turns per layer ascertained. Then the same number of turns is put into each layer. The first layer is carefully placed and is used for a guide for the succeeding layers. Take a coil six inches long, for example, and wind it with No. 20 wire, the gauge of which is increased about .004 of an inch by the insulation. A little calculation would show that the bare wire would fill the space with, say, 200 turns. The insulated wire would fill it with about 146 turns. With the coarser wires, No. 12, for instance, 60 turns of bare wire might be sufficient to fill the space, and about 44 turns of insulated.

Fig. 7 shows the method of winding a "short" ring armature. The core insulation is marked H and the cotton cloth G. The latter is wound as the work is progressed, and prevents the outside wires from getting out of position during the building of the bobbin. Three systems of winding are employed. These are selected according to the work required. The first system is made with 13 turns of the bobbin, and possesses the most torque. The second is made with nine turns and has high speed. The third is made with 12 turns and is the medium range. The armature slots are insulated with fullerboard and mica. The method of securing the wire is shown in Fig. 8, in which I indicates a section of a curved piece of wood, which is sustained between the lips of the projection.

In Fig. 9 is shown a good way to wind a drum armature. This end view indicates how the connectors may be passed from slot to slot, divided



MAGNET AND ARMATURE WINDINGS.

into two layers, one-half being laid next the core, thus forming the lower layer, and the other half forming the top layer, as represented by K and L in Fig. 10. The advantage of this method of winding is that the wires do not cross each other, and a thin disk of insulation can be inserted to form a separation. To remove a coil from a drum wound after this fashion, first lift out the upper part from the slot, then the lower part from below, then remove the conductor above it. Then remove every other upper conductor in the span between the two slots and then the coil can be removed, and if damaged, replaced with a new one.

Fig. 11 shows the method of a packed "straight-out" winding, which is constructed with the coil protruding. The coils form a cylindrical ring at the end of the armature, where they are protected by tape wound on the ring. A metal support is provided for the ring, and this ring is so shaped as to form a part of the disk end which holds the laminæ and armature in place.

The receiver for the Metropolitan elevated railroad of Chicago has asked Judge Showalter for permission to equip eight additional motor cars for use on the three branches. The cost will be $13,000. The additional motors will decrease the minimum headway on the branches to six minutes and on the loop to a minute and a half.

Western Electrician.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO.

TELEPHONE, MAIN 1746.

EASTERN OFFICE: 108 TIMES BUILDING, NEW YORK.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

Illustrated Electrical Patent Record	192

An English writer makes a curious complaint in relation to an American technical magazine. "This is a good number," he writes, "but, as usual, one cannot open it in a rain-shower, however slight, for fear of gluing the pages together." The critic may be very zealous in the pursuit of knowledge, but the ordinary mortal does not stand unprotected in a storm to do his reading.

Electrical men should look to their laurels. In the patent report for March 15th there was a scarcity of electrical patents such as has not been noticed in many years. Heretofore it has been customary to regard the patent issues as an indication of the condition of the electrical industry, but at the present time all indications disagree with the patent department, as there seems to be no reason for the dearth of invention disclosed by this record.

There seems to be no doubt that the overhead trolley will soon be admitted to the downtown business district in the South Side system, as the Chicago City Railway company and Mayor Harrison have reached an agreement for the construction of temporary lines on State street and Wabash avenue. It now remains to be seen whether the people, after experiencing the good results of the electric system, will consent to the retention of the cable in the South Side service.

According to the daily papers a Polish schoolmaster has solved the problem of transmitting photographs electrically, but the latest European exchanges discredit the statements cabled from London and Vienna. It will be necessary, in any event, to await the pleasure of the inventor, as he declines to give any particulars or disclose the methods he employs any more than in the most general terms. The subject is of great interest, however, and information from authoritative sources will be eagerly awaited.

M. Branley has recently shown to the Society of Electricians of Paris some results of experiments in the line of signaling telegraphically without wires. He placed in circuit a tube filled with iron filings, a battery and a galvanometer. In a normal condition the tube offered a very high resistance, but if some producer of electric waves was put in action the conductivity of the tube was rapidly augmented. It was shown that this tube could be made available as a receiver of electric vibrations having their origin at a distance.

At a recent meeting of the International Electrical Society, says the Revue Générale des Sciences, M. Bucherot gave some results of his experiments with industrial condensers. He found that paraffined paper gave excellent results, but the condenser should not be allowed to heat, as its insulation resistance would fall rapidly with a rise of the mercury. A paraffined paper condenser showed an insulation of 2.6 megohms at 37° C., but fell to 700,000 ohms at 50°, and to 100,000 at 80°. A difference of potential of over 800 volts is liable to pierce the insulating paper.

Novelty in conventions of such organizations as the Northwestern Electrical association is not always attainable without sacrificing some valuable features, but it is promised that the plan adopted for this summer's meeting of the Northwestern association will accomplish this purpose. There can be no question as to the novelty and charm of the plan proposed, and it is believed by the promoters that it will ensure the most interesting and successful gathering in the history of the organization. It is an ambitious undertaking, to be sure, and its successful accomplishment can only be brought about by persistent work and unanimous support on the part of the members and friends of the organization. With this fact impressed upon them, it remains only for the promoters to put forth their best efforts and present an attractive programme. The lake trip itself will doubtless be an enjoyable event, and as the points at which it is proposed to stop between Chicago and Duluth are fraught with interest to electrical men, all branches of the industry should have large representations. The cities of Duluth and Superior have extended very cordial invitations to the association, and the representative bodies of those communities are already preparing to make the event noteworthy in the annals of the Northwestern Electrical association and the history of those municipalities.

A correspondent who has just completed a report of an investigation of a municipal lighting plant makes a request that will provoke a smile from those who have had experience with similar undertakings:

> You are perfectly welcome to tear it [the report] to pieces if you do it in a decent way, remembering when doing so that I am not an especial advocate of municipal ownership and also omitting the stale arguments about politics, because there are none in this case.

It is really refreshing to find such trustfulness. Our correspondent evidently does not appreciate the fact that it is politics that the honest advocates of municipal ownership fear, and that a desire for political influence and power for corruption alone influences those who are not actuated by honest motives. The city plant upon which he has made report may not have suffered from the manipulations of local politicians, but the indications are that it did, and that had it not been for their work his services would not have been in demand. However, as the conditions are not all clearly set forth it is scarcely worth while giving the matter further consideration.

Not only do the dictates of common humanity and good business judgment impel street-railway companies to use the best attainable braking and controlling apparatus, but the decisions of the courts show that such a course is imperative as a prudential measure. An instructive case in point is that of Thompson against the Salt Lake Rapid Transit company, which was recently reviewed by the Supreme Court of Utah. The circumstances of this suit are well adapted to point a moral.

It appears that at the time of the accident the motorman saw a well-grown, deaf-and-dumb boy 14 years of age approaching the track, with an evident intention to cross, without seeing the car. The motorman applied the brakes, but they were so defective that they did not work, and he (the motorman) received a shock from the defective apparatus that delayed his purpose for a second. Therefore he could not stop the car until the injury was done, because of the defective brakes. The car ran 50 feet after striking the boy. The company had had repeated notice of the defective brakes and motor, but failed to repair them, and it was shown that if the car had been in repair it could have been stopped within eight feet.

Under these circumstances the court held that the company was negligent in the use of the car. If the company knowingly placed in operation upon the public street a defective car that could not be controlled because the appliances provided for that purpose were out of repair, and the injury complained of was occasioned by such defective brakes and appliances, and the motorman was unable to avoid the effect of the contributory negligence of the boy, because of such defects, then, declares the court, it could properly be said that the company's negligence was the proximate cause of the injury. To this it adds that the company should not be allowed to excuse its own want of reasonable care, and avoid liability, by showing that, prior to and at the time of the accident, it had knowingly been negligent in keeping its car and appliances in order and repair, and that on account of such negligence it was unable to prevent the injury complained of at the time by the use of ordinary care.

The court pointed out that when the company placed its cars upon the track for service a person attempting to cross the track in front of one of them had a right to expect that the usual appliances for starting, stopping and controlling the car were provided. Knowingly placing an electric car upon a track in a public street, and allowing it to run without such appliances for its control, the court holds, is not only gross negligence, but it may amount to criminal negligence in case of injury to one without his fault. When both parties are negligent, the true rule is said to be that the party who last has a clear opportunity to avoid the accident, notwithstanding the negligence of his opponent, is considered solely responsible for it.

Northwestern Electrical Association.

A meeting of the committee of the Northwestern Electrical association was held at Janesville, Wis., on March 14th, to consider the question of holding a midsummer convention. Pliny Norcross, P. H. Korst, Henry L. Doherty and J. M. Hill were present, James R. Dee of Houghton, Mich., being the only absent member. The following resolution was unanimously adopted:

Resolved, That as a committee of the Northwestern Electrical association, we accept the invitation of the cities of Duluth and Superior to visit those cities next June, and that J. M. Hill of Chicago be authorized by this committee to make arrangements with any steamboat company for a summer meeting of said association. to be held en route from Chicago, via Sault Ste. Marie, Hancock and Houghton, to Duluth.

The plan proposed involves a trip by steamer from Chicago to Duluth and Superior, returning by rail. It is probable the Manitou will be secured for the event. The time consumed by such a trip, including two days' convention at Duluth and Superior, would be between five and six days. It is proposed to hold this convention immediately following the meeting of the National Electric Light association at Chicago on June 7th, 8th and 9th, and it is hoped that many members of the latter body will take advantage of the opportunity to make a lake trip between Chicago and Duluth. The plans provide for leaving Chicago not later than Saturday, June 11th, and with this arrangement Mackinac Island would be reached early Sunday morning and Sault Ste. Marie shortly after noon. One feature of the programme is a four-hour stop at this place to enable the visitors to inspect the ship canal and other points of interest on the American and Canadian sides. The party will leave Sault Ste. Marie Sunday night, arriving at Hancock Monday morning. A visit to the mines of the Calumet and Hecla Mining company has been arranged. The ladies of the party will remain at Hancock and Houghton, where entertainment will be provided. An early start will be made from Hancock Monday afternoon in order to reach Duluth Monday night.

The expense of the entire trip, including steamer, meals, state rooms, hotels at Duluth and Superior, railroad fare returning, including sleeping-car accommodations and dining car, will not exceed $43, according to the committee's estimate, which is based on direct proposals made by the steamship company and reduced rates of $2, $2.50 and $3 per day promised by the hotels at Duluth and Superior. One-third rate by rail returning from Duluth to Chicago has been secured from the Western Passenger association.

It has been suggested that Frederick N. Bosson, chief electrician of the Calumet and Hecla Mining company, be invited to read a paper on the subject of "Reduction of Ores by Electricity." Such a contribution would be an attractive feature, especially in view of the visit of the association to the copper country and Mr. Bosson's eminent position in electrolytic work.

President Copeland has appointed J. M. Hill, W. W. Low and F. E. Donohoe of Chicago a committee of arrangements for the entertainment of the delegates.

Electric-light Trimmers Not Public Officers.

A person employed by a city council to trim lights in its electric-light department, the Supreme Court of Ohio holds, in the recent case of the State against Anderson, 49 Northeastern Reporter, 406, is not a public officer. Neither is an engineer employed to run an engine in such department. The explanation of this is found in the case of the State against Jennings, decided at the same time, where the court says that to constitute a public office, against the incumbent of which will lie what is termed a writ of quo warranto, to test his right to hold such office, it is essential that certain public duties, a part of the sovereignty of the state should be appointed to it by law, to be exercised by the incumbent in virtue of his election or appointment to the office thus created and defined, and not as a mere employe, subject to the direction and control of someone else. The practical application made of this doctrine was to base on it a refusal of the writ of quo warranto sought for the purpose of ousting certain trimmers and an engineer from their employments.

Pontiac-Flint Electric Railway.

A company has been organized to build an electric railway 40 miles long to connect the cities of Pontiac and Flint, in Michigan. George E. Taylor of Flint and J. E. Sawyer and Hon. S. W. Smith of Pontiac are interested in the enterprise. The road will pass through a well cultivated, fertile and prosperous section of the state, the route surveyed touching the villages of Drayton Plains, Waterford, Clarkston, Ortonville, Goodrich, Atlas and Grand Blanc. Some of these places are not on any steam railroad line, and a good passenger and freight business is anticipated for the new road. The track will be laid with 70 pound steel T rails, and it is expected that grading will be begun in a few weeks. A power house at either end of the line is contemplated, but the engineering plans appear to be still incomplete. Mr. J. E. Sawyer of Pontiac can give more detailed information about the project.

Toronto Magnetic Observatory.[1]

By R. F. Stupart.

The importance of obtaining a correct knowledge of the elementary facts of terrestrial magnetism, for the purpose of supplying a foundation whereon the advancement of that science on inductive principles may be based, has for long been strongly and extensively felt.

From an early period of the meetings of the British Association for the Advancement of Science, the interest of terrrestrial magnetism had received no inconsiderable share of the attention and exertions of its members. In the year 1834 a magnetic survey of the British Isles was commenced and carried through in the two following years by the joint labors of five of its members. In 1835 the association called for a report from one of its members, on the state and progress of researches regarding the geographical distribution of the magnetic forces on the surface of the globe, proposing to ground on the preliminary examination an application to the government to aid in the prosecution of the inquiry in remote parts of the earth, unattainable by the means at the command of the association itself, or of its individual members. This report, presented in 1837, was taken into consideration at the meeting of the association, at Newcastle, in 1838, and a memorial was addressed to the government which, being favorably received by her majesty's ministers, originated the naval expedition equipped in the following year for a magnetic survey of the high latitudes of the southern hemisphere. Deeming the opportunity a fitting one, the British Association availed itself of the same occasion to solicit the attention of her majesty's government to the expediency of extending the researches to be accomplished by fixed observatories to certain stations of prominent magnetic interest within the limits of the British colonial dominions. The stations named were Canada and Van Diemen's Island, as approximate to the points of the greatest intensity of the magnetic force in the northern and southern hemispheres; St. Helena, as approximate to the point of least intensity on the globe, and the Cape of Good Hope as a station where the secular changes of the magnetic elements presented features of peculiar interest.

The committee recommended that the proposed colonial establishments should be placed under the general supervision of the Ordance Department of the army. The government having expressed a desire that such extensive arrangement involving a considerable expenditure should be strengthened by the concurrent support of the Royal Society, a deputation was appointed to express the cordial participation of that society in the recommendation both of the naval expedition and of the fixed observatories. Arrangements having been completed, Lieutenant Charles James Buchanan Riddell, R.A., was selected for duty in Canada, who, leaving his detachment, consisting of four non-commissioned officers of the artillery, to embark with the instruments on a vessel bound direct to Quebec, proceeded himself to Canada by the more expeditious route of the United States, and having waited on the governor-general at Montreal to present a letter of introduction with which he had been furnished by the master-general of the ordnance, and communicated with the commanding engineer, to whom he was the bearer of instructions and authority to build an observatory, he proceeded to examine different localities which were suggested as convenient sites. The preference was finally given to Toronto, where a grant of $2\frac{1}{2}$ acres of land belonging to the University of King's College was offered by the council of the University. The first observatory building was of logs, rough-cast on the outside and plastered on the inside; it was completed during the summer of 1840 and observations were begun in September. The operations of the observatory as an imperial establishment were brought to a close in the early part of the year 1853, and were resumed under the authority of the provincial government in July of the same year.

In the autumn of 1853 the present observatory was commenced, to take the place of the old building. Very great care was taken during construction to insure all the stone used being entirely free from magnetism, and all nails and fastenings were of either copper or zinc. For 23 years the position of the observatory was, as far as is known, faultless, and observations were carried on systematically and carefully, and results given to the scientific world, which, with those obtained under the old military regime, have made the Toronto Observatory famous in the history of terrestrial magnetism.

In 1876, however, trouble began with the building of the School of Science, which institution, however, being principally of brick and wood, caused but very small changes in zero values, which could be allowed for. Then followed, a few years later, electric light circuits which produced a change in the force instruments whenever the current was turned off or on; this difficulty was in part overcome by the light company courteously agreeing to arrange its wires in the vicinity of the observatory in such a manner that currents should counteract each other. The next difficulty occurred when the addition was given to the School of Science, tons of iron being used in the construction of that building in an all too-close proximity to the magnetic instruments, and much time and labor have been required to determine the precise effect of this "iron mine" on the various instruments. It was not, however, until the autumn of 1892, when the trolleys began to run, that we began to suspect that sooner or later the Magnetic Observatory would have to be removed to another site.

The magnetic instruments in the observatory consist of those brought out by Lieut. Riddell in 1840, of which eye readings have been taken six times each day, and of another set of similar instruments, consisting of a bifilar, for the measurement of the horizontal component, a balance needle for the vertical force and a declinometer, all of which record photographically.

Electric cars first ran in Toronto on August 17, 1892; the line first put in operation was that on Church street, which was followed on September 5th by King street, between George street and Dufferin street. During the first few weeks, while a very small vibration of the needle was discernible on the v. f. curve, it was generally almost inappreciable, and it was not until September 20th that the movement increased to an extent sufficient to really impair the value of our magnetic curves; a marked increase of current must have been used on that day and afterward. On October 10th the cars first ran on Yonge street, and there was only a very small increase in vibration, but a decrease of about .000070 of a dyne was observed when the current was on. About 10 a. m., on January 14th, there was a marked increase of vibration, and the vertical force increased about .000200 one dyne. This disturbed period was only temporary, and shortly after 5 p. m. of the 17th there was a reversion to the smaller vibrations, which continued until May 15th, when very large vibrations began again and continued with varying intensity during the summer, while the decrease of the v. f. with the current ranged from about .000200 to .000500. This disturbance was very great between September 12th and October 17th and at intervals during the following year, but there was no radical change in conditions until December 17, 1894, when a decrease of v. f. while the current was on was changed to an increase, this occurring when the cars first ran on McCaul street. Throughout 1895 the vibration and amount of permanent deflection were very nearly as they have been since, but on October 15th the increase of v. f. with the current was again changed to a decrease. This occurred at the time that the railway company made certain changes in the feed wires. It is noticeable that, although several changes occurred in the v. f., it at times has been less with the current on and at other times greater. The horizontal force showed a steady decrease on all occasions with the turn on of the current, which during the past two years has been .000200 to .000500. No appreciable deflection of the declinometer magnet can be noted, the only effect being a continuous vibration which has rendered the curves very ragged and difficult to read with accuracy.

A study of the traces during the times that the various electric lines were put in operation shows that with the currents ordinarily used there is little effect at three fourths mile, and a further survey with a portable instrument affords further evidence in the same direction; it has, therefore, been determined to remove the magnetic instruments to a point distant two miles from any probable trolley route and about nine miles from the present location, and continue what is certainly the most valuable and extended magnetic records outside of Europe.

1 From the Canadian Engineer.
2 The history of the establishment of the observatory at Toronto is taken from the early report.

The Trolley Wins in Chicago.

It is admitted that the Chicago City Railway company won a notable victory on Monday when negotiations were practically closed between the city and the company by which the latter will be able to bring its trolley cars downtown during the progress of the track-elevation work at Sixteenth and Clark streets.

The company secures its permit for trolley poles and wires in Wabash avenue and State street from Twenty second to Van Buren street. From Van Buren street north to Lake street, the northern terminus sought by the company, the route will be circuitous, the State street electric cars following Van Buren to Wabash avenue, Wabash avenue to Madison, Madison to Michigan avenue, Michigan avenue, to Randolph, Randolph to Wabash avenue and thence south in Wabash avenue to Van Buren, where they will return to State street. This scheme keeps the trolley under the elevated loop structure in the downtown district, except for two blocks in Michigan avenue and two in Madison street. The company already has permission to use the streets under the Union elevated loop structure, by virtue of an ordinance apporved by Mayor Swift. The mayor agreed to issue a permit on condition that the company enter into an iron clad written agreement to remove the poles and wires at the direction of the mayor, not to ask for an injunction restraining the city removing them at any time, and also not to ask the council for an ordinance to retain the poles and wires during the time they are standing.

DEVELOPMENT OF THE TELEPHONE FIELD.

Telephone News from Iowa.

[Special correspondence of the Western Electrician.]

Waverly, March 21.—The Cedar Valley company is about to build a line from Allison to Hampton. Farmers in Emmet County contemplate building a line to connect several farms with Armstrong.

The Standard Telephone company of Waukon will extend its lines to all points in Winnesheik County, and also to Elkader via Farmersburg and McGregor.

The C. R. & M. Telephone company will extend its system to Marshalltown. It is now trying to establish an exchange at Marion.

The Mississippi Valley Telephone company contemplates building a line to Dubuque via Savannah, Ill.

The Western Electric Telephone company, of which J. F. Cass is president, will construct at least 500 miles of new toll lines and several exchanges, principally in Minnesota. This company is doing extensive work in Kansas and Missouri. The Interstate Telephone company, with no definite headquarters at present, expects to build extensively in Southern Iowa and Nebraska.

The Des Moines telephone exchange is gaining daily in subscribers. The same is true at Marshalltown and Cedar Rapids. Reports indicate that at all points the Bell company is falling behind.

E. T. Keim is building an exchange at Centerville.

An opposition exchange will be built at Muscatine and, if a franchise can be obtained, at Davenport and Dubuque. Ample capital is back of this movement.

The Iowa Telephone company will build a line from Guttenberg to Dubuque. It is the intention of this company to have every county seat in Iowa connected by its long-distance system soon. It will also extend its lines via Belle Plaine to Marshalltown, build two circuits from Dubuque to Sioux City and connect with the Northwestern Telephone Exchange company at Austin and Prosper, Minn. Connections with the Wisconsin Telephone company's lines are contemplated at Boscobel, the Iowa company building from Prairie du Chien. Extensions will be made from Northwood.

Several changes have been made and others are now contemplated in the staff of the Iowa Telephone company, which is, of course, a Bell concern. J. R. Lane, who has been president of the company, will be succeeded by C. E. Yost of Omaha, Neb. T. von Rolf, assistant superintendent, has resigned. to take effect April 1st. He has served the company for the last 16 years. C. R. Wood has been placed in charge of West Union and Decorah. and A. Hooper has been placed in charge of McGregor, Waukon and Prairie du Chien. F. H.

Telephone Regulation Rejected in Kentucky.

A telephone bill was proposed in the Kentucky Legislature, which has just completed its deliberations, by the Owensboro Harrison Telephone company and was supported by the independent companies throughout the state, but it failed, greatly disappointing all classes of people throughout the state. A dispatch from Frankfort in the Daily Owensboro Messenger thus explains the defeat of the measure:

> The telephone bill requiring uniform charges for telephones in cities of the same class, which passed the Senate ten days. ago, failed to get through the House The efforts to pass this bill were fiercely resisted by the powerful Bell telephone lobby, but only the name of Joe Blackburn finally defeated it. A clear majority favored it, but the rules committee, aided by Speaker Beckham, refused to let it come up on account of Blackburn, who was employed by the Bell company to come here and make a speech before the committee against the bill.
>
> Notwithstanding Blackburn's speech, both the Senate and House committees unanimously reported in favor of the passage of the bill and it passed the Senate unanimously, but was blocked in the House.
>
> The main argument against the bill was that Blackburn was to get [illegible] fee in the event of failure of the bill, and his friends in the House wanted him to earn the money

This announcement has stirred the wrath of other Kentucky gentlemen, and, as a result, Senator Blackburn has been roundly denounced for his part in the proceedings. Here is a sample of editorial denunciation from the Daily Inquirer of Owensboro:

> A measure of the Kentucky Legislature is given in the report of the fate of the telephone bill the object of which was to cause telephone companies to [illegible] a uniform tariff in cities of the same class. Both committees reported unanimously in its favor and there seemed to be no doubt of its passage until it was learned that Joe Blackburn had been employed to lobby against it and was to receive [illegible] in the event of its defeat. Then the table turned and the bill was lost. We are told by an eminent [illegible] authority that "the main argument against the bill was that Blackburn was to get a fee of [illegible] in the event of the failure of the bill and his friends in the house wanted him to earn the money." [illegible] to any one of contempt too severe for an action like this. [illegible] the common or dinary, everyday kind [illegible]

Evart Telephone Exchange.

The Evart, Mich., telephone exchange was started in 1896 with nine [illegible] on a grounded system. The number has [illegible] to 33, the limit of the present board, but negotiations are now pending for the installation of a 100-drop board, with a fair prospect that a large portion of it will be taken up the coming season. The system has been changed to common return and when the new board is put in another change will be made to complete metallic circuits. The Citizens' Mutual Telephone company of Grand Rapids, Mich., connected its lines to the Evart exchange a year ago, and the subscribers of the Evart exchange consequently connect with 130 different towns in Michigan over the Grand Rapids system.

Telephone Extension in Chicago.

It is taken as a gratifying evidence of the return of business confidence that on March 10th the number of calls answered in the exchange of the Chicago Telephone company reached the number of 226,221. This is believed to be the largest number of messages handled in any exchange in the world in one day. New York has touched 190,000, and it is not thought that any of the foreign exchanges have reached that figure. General Manager Hibbard states, too, that while the number given for March 10th is the highest recorded, it is not very far from expressing the daily average of messages handled at the present time. It is interesting, for the purpose of comparison, to note that on March 10, 1897, the calls answered were 189,993. The 226,221 calls of March 10th last figure out an average of 18 calls for each telephone connected with the main office and branches of the company. However, if the residence telephones were excluded from the computation the average would be much higher.

Work is under way on the two new down-town branch exchanges of the Chicago Telephone company in the Title and Trust (Washington street) and Manhattan (Dearborn street) buildings, but it will be a month or so before they are ready for use. Land has been purchased for a new telephone building for the company on the West Side, near Madison and Peoria streets. The structure will be devoted to the West Side exchange and will be built this year.

Telephone Situation in Elkhart.

The independent telephone interests in Elkhart and throughout Indiana are actively engaged in extending the system in that section. The Elkhart company recently printed its list of subscribers in a daily newspaper and requested the Bell company to follow its example. Some interesting statements are presented in the announcement of the local concern:

> Three years ago there were in Elkhart 100 telephones at an average rate of $42 per year or 42 cents for every possible connection.
>
> The home company, now two and one half years old, has 355 subscribers at an average rate of $21, or a trifle less than six cents per year for every possible connection. All this in the face of nominal rates and free service competition, thanks to the loyalty and fidelity of our friends and neighbors.
>
> A similar growth and revolution is visible over the entire state. The people now have 137 exchanges against 27 by the old company, 1,500 toll points against 307 by the old. The home companies own 4,600 miles of toll lines and fully 20,000 telephones in Indiana alone. and we are not aware of one financial failure among them. Some adjoining states make even a better showing.

The obnoxious features of the Bell policy are attributed by the Elkhart company to the influence of the parent company. "The general policy of defiance emanates from Boston and not from Chicago or Indianapolis," it says.

European Telephone Statistics.

Some interesting statistics have been compiled showing the number of telephones in use in several European countries. The returns from Norway, Denmark, Finland, Great Britain and Portugal are incomplete. Turkey and Greece have no telephone systems. In the list of nations thus far reported Germany occupies a commanding position. Following is the data thus far gathered:

Country.	No. of exchanges.	No. of instruments.	Ratio of instruments to population.
Germany	534	131,577	1 to 397
France	307	31,681	1 to 1,216
Switzerland	295	23,146	1 to 129
Sweden	293	42,354	1 to 115
Austria	124	18,050	1 to 1,318
Luxemburg	57	1,356	1 to 160
Italy	54	11,518	1 to 2,629
Russia	53	16,050	1 to 6,988
Spain	48	10,810	1 to 1,597
Hungary	36	8,458	1 to 2,168
Holland	31	7,680	1 to 615
Belgium	15	9,190	1 to 682
Roumania	6	243	1 to 13,616
Bulgaria	5	213	1 to 13,616

Western Telephone Construction Company.

There has been virtually a reorganization of the Western Telephone Constuction company of Chicago. Mr. Keelyn remains president of the corporation and he has also been made general manager of the business, with complete power in all departments. B. F. Stewart has been chosen secretary.

The company has decided upon a much more aggressive policy than that heretofore followed. It is already preparing for a large increase in its business, and its factory space will be at once enlarged 50 per cent.

The Telephone Situation.

By J. J. Nate.

Part III.

State Supervision

Referring to a means for establishing a uniform class of toll-line and exchange service, I have to say that no better plan can be adopted than that which the Bell company followed for several years; the employment of state or division superintendents, whose business it is to travel from point to point, and, after an inspection, recommend all necessary changes. Such men should be employed by the several state associations, and salaries made up among the exchanges in whose interest they are employed. They should be thoroughly experienced telephone men, of fair executive ability, and their recommendation to the owners of exchanges for alterations which would tend to bring about a uniform service should at all times be given heed to and the remedy applied at once. It will be seen that by such an arrangement a good salary can be paid at a very small cost to each exchange company, and thus able men can be secured for this important work.

Another very good means of accomplishing in part a similar result is concerted action on the part of home companies and the organization of state associations on a somewhat different basis than at present in vogue. Each state organization should assemble at least twice a year, while an international convention should be held at least once a year. I well remember in the first years of the Bell company's experience, when all were interested alike, how much good was accomplished in this way, and valuable information secured at very small expense. In state associations and in the employment of district superintendents, manufacturing companies should certainly have no voice and no interest. The business of a telephone manufacturing company is simply to sell apparatus. Operating companies do not need their assistance or direction in any particular whatever. As a rule, manufacturers are not more practical in exchange work than are promoters, and their advice is of little if any value, and sometimes proves most expensive, as recommendations are too often based on personal interest.

Patent Situation.

For three years this bugaboo has been prominently forced on the telephone public by the Bell company and its allied interest, and has undoubtedly proven a stumbling block to many, who, from timidity or want of opportunity, could not thoroughly inform themselves as to its true status. As a matter of fact, what is the situation? Simply this: It differs in no particular from other commercial, manufacturing or operative interests. Hardly a day passes during which some court or another is not called upon to decide the merit of patents which rival interests own, and which they wish to protect, and it is not at all strange that in the telephone business the same condition of affairs should exist, and, while I know that many of the patents owned and controlled directly or indirectly by the Bell company are of value, I am also perfectly satisfied that a large percentage of their so-called strong patents are entirely without merit and inoperative. It is true that the issue of a patent establishes an individual right to protection under the laws of our country, but the applicant must prove invention of a new and useful art, process, machine, manufacture, composition of matter or improvements thereon. How often this is done may be best illustrated by quoting from the "Report of the Commissioner of Patents for the Year 1893:" "Of 988 court cases reported in the Official Gazette, between 1886 and 1892, wherein patents were in litigation, 436 patents were sustained and 552 were declared invalid in whole or in part. Of the number declared invalid. 428 were by reason of some fault in the office, and 124 on account of evidence brought to light of which the office had no knowledge before granting the patents. * * * * Approaching the subject from another side, I am furnished with the result of examinations as to the validity of the claims in 10 patents, taken at random, where the searches in this office were made by a well-known law firm. These patents contain 50 claims, of which 35 were considered and reported to be old."

The question of infringement is separate and distinct from that of patentability. The courts deal only with the former. In view of the results shown in the report from which I have quoted, it is certainly reasonable to assume that in the telephone business the percentage of valueless patents should be, if anything, even greater.

Furthermore, the telephone at an early date seems to have been but poorly understood by the Patent Office, and many patents were issued where the magic word "telephone" seemed apparently to convey novelty and originality of invention, no matter in what sense applied; while the fact has to some extent been lost sight of that telephone, telegraph, electric-light and power work all belong to the same class--in other words, the same conditions for distribution of energy and operation enter into all, differing only as to the work for which

the apparatus is designed. As an illustration of the value of patents issued under such conditions, I may quote in part Judge Showalter of the United States Circuit Court at Chicago (see opinion handed down February 10, 1897, Western Electric company vs. Western Telephone Construction company, alleging infringement of the celebrated Watson patent). "In view of the state of the art, my judgment is that there is no novelty or invention in any of the eight claims, nothing more than the use of clever mechanical expedients in arranging a subscriber's outfit. The bill is therefore dismissed for want of equity." Many similar decisions can be cited having direct bearing on telephone and electric patents. From a careful examination and comparison of British and American patented invention of telephone apparatus, going back to the first patent granted Alexander Graham Bell, I gather sufficient information to feel quite sure that the independent telephone companies of this country have nothing to fear on that score, particularly if judgment is used in the selection of apparatus and a fair knowledge of the subject acquired before purchasing. There is no doubt that many good and valuable patents, controlled by the Bell company, are to-day being infringed by thoughtless or unprincipled manufacturers. I do not intend to imply that because a patent has issued, manufacturers should keep hands off, but I do assert that a reckless use of apparatus, without the advice and sanction of well-informed legal counsel, is a practice which must in the end cause needless expense both to manufacturer and purchaser alike.

Fighting the Bell Company.

In Simon Sterne of New York the Bell interests have found a foeman worthy of their steel. Mr. Sterne has persistently fought the local telephone company and thus far has had the best of the scrimmage. Last week the telephone people tried a new dodge. Counsel for the Metropolitan Telephone and Telegraph company asked Justice Giegrich in the Supreme Court March 18th to discontinue an action brought by Simon Sterne to enjoin the company from removing a telephone from his law office. Justice Giegrich reserved his decision. The action was begun in 1895, when the telephone company served notice on Mr. Sterne that, with a number of other subscribers, he must pay $240 a year for his telephone instead of $150. The company was dissolved in 1896, and the business was taken over by the New York Telephone company.

W. B. Hornblower, who appeared for Mr. Sterne, opposed the motion, and asked that the New York Telephone company be added as a party defendant to the suit. He said that the act under which the old company dissolved especially provided that it should continue in existence for the purpose of discharging its obligations, and could sue or be sued. Mr. Hornblower said that Mr. Sterne wanted the new company added as a defendant in order that when the suit came up for trial a final adjudication might be made on the question.

Counsel for the Metropolitan company said that he could not consent to or oppose the motion to add the new company as a party defendant, as he did not appear for that corporation.

Mr. Hornblower said: "The New York Telephone company not only has taken over the business of the old company, but is now the owner of the very instrument now in dispute. We have the same right to bring in the new company as we would have to bring in the purchaser of a piece of property which had been transferred to get the former owner out of the consequences resulting from an action against him for maintaining a nuisance."

Southern Telephone Notes.

A correspondent at Greenville, Tenn., writes that the independent movement is strong in East Tennessee and that independent telephone exchanges have been established from one to three years in Knoxville, Morristown, Greeneville, Jonesboro, Johnson City, Bristol, Elizabethton, Newport, Maryville, Clinton and Coal Creek; that they are all connected by long-distance lines, and that they are cutting "deep holes" into the heretofore large revenues of the "East Tennessee (Bell) Telephone company."

A company is being organized at Winnsboro, S. C., to establish a telephone system. J. M. Beaty is interested in the scheme.

The Versailles (Ky.) Telephone company has been organized with a capital stock of $5,000. B. B. Smith is the president of the company.

Increase in business has necessitated an addition to the switchboard of the Las Vegas Telephone company of Las Vegas, New Mexico. The company added 20 drops to the board on February 1st, and has five of them already in use.

The Mutual Telephone company has been organized at Ronceverte, W. Va., with an authorized capital of $10,000, to construct a telephone line from Marlinton to Monroe Academy, Pocahontas, Frankfort, Lewisburg, Ronceverte and Greenbrier via Organ Cave, Pickaway and Union.

The People's Telephone and Telegraph company of Knoxville, Tenn., is planning to put up a magnificent fireproof building in which to house its central office, electrical laboratories, general repair shops and general offices. It has also perfected its plans for placing its wires in conduits throughout the business section of the city. The company hopes to begin the work proposed by the first of next year, and have it completed in sufficient time to occupy the first of June of next year. The People's company is purely a home institution, and it is stated that the capital required to accomplish this improvement will be furnished by Knoxville men.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Rock Island, Ill., telephone exchange, which was burned out some time ago, has resumed operations.

A new telephone system will be constructed at Sault Ste. Marie, Mich.

The Jefferson County Telephone company will extend a line to Batavia and Packwood, Ia., if granted a franchise at the spring elections.

The telephone companies at Boone and Marshalltown, Ia., will extend their lines to connect their systems this spring.

A telephone line will be built from New Prague, Minn., to Wesley, Minn., this spring.

A telephone line is to be constructed between Ringgold, Watterson and Caledonia, Ia. A. L. Case is general manager.

The Mississippi Valley Telephone company franchise has been passed by the Assembly committee on streets.

It is reported that the Iowa Telephone company offers to reduce its rates at Muscatine, Ia., about one-half, if the Hubinger company is refused a franchise.

It is again rumored that the head offices of the Iowa Telephone company are to be removed from Davenport to Des Moines.

The Western Electric Telephone company proposes to extend its lines west from Pipestone, Minn., to Madison, S. D.

The Iowa Telephone company has made a rate of $1 per month for a six-party line service at Des Moines for residences.

The Forman Telephone company, which operates the exchange at Lisbon, N. D., has reduced rates to $1.50 and $1 for business houses and residences. The projected local company has been abandoned in consequence.

Mr. Hungerford, of the Billings, Mont., telephone system, has made a proposition to the council of Miles City, Mont., to put in an exchange there.

The Union Telephone company has been organized to connect Wautoma, Wis., with Hancock, Plainfield and other points. Work will be begun in the early spring.

The Spokane and British Columbia Telephone company is constructing lines between the Columbia River and Republic, and will soon begin work on a line between Rossburg and Grand Forks, B. C.

Albia, Ia., will vote March 28th on granting a franchise for a telephone exchange.

The Northwestern Telephone Exchange company is arranging for a right-of-way to Princeton, Minn.

T. F. Robinson of Tracy, Minn., has been granted a franchise for a telephone exchange in St. James, Minn. Mr. Robinson has exchanges at Tracy, Marshall and Pipestone.

The Perry Telephone company proposes to connect with Guthrie Center, Ia., and establish an exchange there.

The telephone company of Anaconda, Mont., inaugurated night service March 15th.

J. C. Hubinger of Keokuk, Ia., has been granted a franchise for a telephone exchange in Muscatine, Iowa.

M. Plank and Dr. F. A. Wood of Hancock, Wis., propose a telephone line to connect Plainfield, Hancock, Coloma, Coloma Corners and Wautoma, Wis.

The stockholders of the Richland County Telephone company and the Grant County Telephone company held a meeting in Richland Center, Wis., recently and organized a new company to conduct the business of both concerns and build several hundred miles of new lines. The consolidated company will be called the Union Telephone company, and will have a capital stock of $100,000. It now owns 650 miles of toll lines and [illegible] good exchanges. The following named officers [illegible] elected: President, J. D. Holford, Bloo[illegible] vice president, C. H. Pease, secretary and treasurer, L. M. Pease; directors, A. M. Stratton, G. C. Marlo, Bloomington; Theo. Wheaton and J. Robert Coumbe. This company, since its reorganization, is considered one of the strongest in the state outside of the Wisconsin Telephone company.

Telephones and Railroads.

[illegible]

In the United States nearly 800,000 telephones are now in use, with 600,000 miles of telephone wire, 350,000 telephone stations, and it is said, nearly 3,000,000 telephone messages daily. In many cases where formerly the transaction of business involved a railroad journey, the telephone renders it unnecessary, and accordingly the passenger receipts of railroads have suffered to a considerable extent, at least their normal growth has been checked. It is noticeable that where the telephone service is imperfect or undeveloped this effect is not marked.

Independent Telephone Movement on the Pacific Coast.

An esteemed correspondent writing from Sacramento furnishes the following interesting information respecting the progress of the independent telephone movement on the Pacific Coast:

"I have often felt that the telephone companies of the East might find some interest in knowing that the Capital Telephone and Telegraph company of Sacramento, Cal., has been engaged in lawsuits with the Western Electric company of Chicago and the Sunset-Bell company of California since October, 1895. With the former, one suit was on the Watson automatic switch, which has been dismissed, the other being on the use of the multiple switchboard. The latter case was argued on November 11th, 12th and 13th, in the United States Circuit Court in San Francisco, by Mr. Roberts of Boston, George P. Barton of Chicago and E. S. Pillsbury of San Francisco, supported by Expert Scribner for the complainant, with John H. Miller of San Francisco, Charles C. Bulkley of Chicago and L. T. Hatfield of Sacramento for defendant. No decision has yet been reached, but whatever it may be it cannot affect the operation of the local exchange, as it has never worked under anything but the 'trunking' system. The suit with the Sunset-Bell company, which should have been decided weeks ago, was relative to the use of its instrument. After transmitting a number of territorial messages for the Capital company the Sunset company refused to give further service in that direction, claiming that such messages were not upon the Capital company's own business and that it had violated its contract. The Sunset company demurred to the complaint, but was overruled and compelled to make answer. Since the overruling of demurrer the Sunset company allows the Capital company the use of the instrument for all purposes, repeating messages for subscribers throughout the state, etc. While the Pacific Coast is a little backward in the number of its independent telephone exchanges, Portland, Oregon, San Jose, Santa Cruz and Sacramento, Cal., being the only ones, I am satisfied it will not be long till San Francisco has a powerful organization to meet the Pacific-Bell in its great stronghold, as also will Los Angeles."

Bellamy's Ideas in Practice.

By E. C. Dickinson.

In Augusta, Ga., an automatic telephone exchange has been installed about a year. It is needless to say that the Bell people fought hard to hold their own, but the automatic company, with local capital and a mutual interest, opened and grew in spite of all efforts on the part of the old company. When the fight was hottest Sam Jones appeared upon the scene and opened his meetings in an old warehouse with long rows of rough planks as seats, and heaps of sawdust on the floor, presumably to save the knees of his congregation. Many good, bad and indifferent people did not take kindly to the accommodations furnished in the tabernacle, as it was called, and staid away.

At this juncture the electrician of the Automatic company came to the rescue and placed two long-distance telephones on two wooden posts in front of the platform in such a way as to catch the voluminous outbursts of the speaker.

Sam Jones was given a number, and anyone of of the 350 subscribers then being served could call up the tabernacle and hear a sermon while sitting quietly at home. The novelty attracted the people and as many as 250 subscribers listened to these sermons over the lines at one time. When the speaker stood directly in front and within 10 or 15 feet of the transmitters, the sermon could be heard very distinctly. The music, which was at least 25 feet from the telephones, was very clear and loud, musical sounds, as is well known, being much more readily transmitted than spoken words.

The Bell people were in the field, but with their limited number of cords they could only accommodate about 20 people at a time.

It is not incredible to predict that some day, instead of depending on a tri-daily paper for news three or four hours old, we will settle back in our easy chairs and listen to the events of the hour.

COMMUNICATION.

Telephone Taxation in Georgia.

To the Editor of the Western Electrician:

"I desire to direct attention to the unjust and burdensome tax which the Legislature of Georgia put upon telephones some years ago. The amount is $1 for each instrument, which, in addition to city taxes, makes it hard on independent companies which have cut prices so low that there is little profit remaining. We hope to get this law repealed at the next session of the Legislature if the independent interests will all take hold and work in harmony.

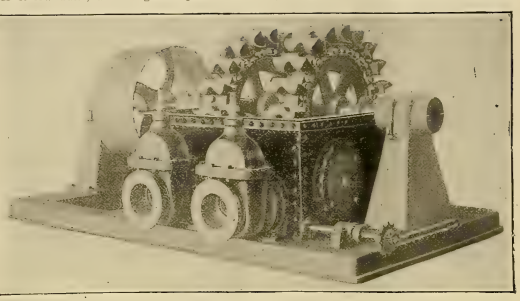
The law was made when the Bell company had a monopoly and charged extortionate prices.

W. E. WHITEHEAD.

Carrollton, Ga., March 5, 1898.

Interesting French Power Plant.

A striking example of the utilization of water power made possible by wheels of the impulse type is presented in the arrangements recently made for power in the textile goods factory of M. Benoist Cadet Fils in La Bastide, a town south of Bordeaux in the Department of Tarn, France. Here a steam engine which formerly was used to furnish the power for the entire factory is now held in reserve for periods of low water, and the greater part of the

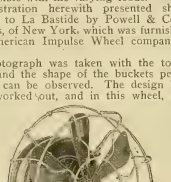


INTERESTING FRENCH POWER PLANT.

time power is furnished by a 36-inch twin impulse wheel, working under a head of 128 feet at 285 revolutions per minute, and developing 40 horse power. The use of contracting nozzles makes a high efficiency possible with the varying loads.

The illustration herewith presented shows the wheel sent to La Bastide by Powell & Colne, export agents, of New York, which was furnished them by the American Impulse Wheel company of the same city.

The photograph was taken with the top casing removed, and the shape of the buckets peculiar to this wheel can be observed. The design has been carefully worked out, and in this wheel, as in all



GENERAL ELECTRIC FAN MOTOR.

others made by the American Impulse Wheel company, the mechanical workmanship is seen to be excellent.

The high efficiency of the wheels made by this company is due to the close attention and study which its engineers have given to every detail and to the great care exercised in manufacturing. A prime mover with so low a first cost, and almost negligible expense for repair, requiring little or no attention while running, is an attractive one to large number of manufacturers who are at present burdened with heavy expenses in connection with their motive power.

The possibilities of the electrical transmission of energy are now so great that many concerns might at comparatively small expense utilize water powers even though they are located at considerable distance from their establishments. All inquiries on this subject which the American Impulse Wheel company receive have the careful consideration of their engineers, and as full information is sent in reply as the data presented will permit.

General Electric Fan Motor.

The '98 models of the General Electric company's fan motor are announced as the latest of a long line of successful designs. These fan motors are built for both alternating and direct-current circuits.

That for alternating currents, shown by the cut, is an induction motor, carefully proportioned in all its parts as are the larger machines which this company builds, except as to air and bearing under continuous operation being absent from the small as from the large. The cast-iron frame which supports a single long bearing are bolted the soft iron laminations which make up the field core, provided with inwardly projecting teeth to form the poles on which are placed the field coils wound with an ample quantity of wire and thoroughly insulated. The armature is built up, also, of soft iron laminations, assembled on a brass spider, but has no insulated wire. Bare copper rods run through the core, and are riveted into disks at each side. Rotation being produced by inductive action, no commutator or brushes are required. The armature overhangs the bearing, and, with the fan, rotates well balanced on the single bearing. An automatic oiling device gives perfect lubrication without oil throwing, and this, together with the long bearing, ensures a continuous cool operation. The alternating fan motor is built for 52 and 104 volts, 60 and 125 cycles, and is provided with a speed-regulating device consisting of an inductive resistance cut in or out by a three-point switch. Movement of the switch over the first two points gives full speed and half speed and on the third cuts the motor out of circuit. No additional switch is necessary.

The direct-current fan motor is as equally compact and carefully designed as that for alternating currents, and in appearance and general construction closely resembles it. Laminated soft iron of the best quality is used throughout for the magnetic circuits; all windings are thoroughly insulated, and commutator connections carefully made. As in the alternating motor, fan and armature revolve in a single, long, self-oiling bearing. The commutator is completely enclosed, and the carbon brushes encased in small tubes, which are readily unscrewed for inspection. A regulating switch provides for variation of speeds. The alternating-current fan motor may be, if desired, mounted on trunnions to allow of adjustment of the fan to blow in any direction. The motors are finished in black enamel, the fan guard and trimmings in polished nickel.

Potential Transformers.

Potential transformers are designed to furnish current for either voltmeters or wattmeters. In common with other manufacturers, the General Electric company has heretofore mounted its smallest standard lighting transformer on a slate or marble base, and supplied it to furnish current for instruments without changing its rating as a lighting transformer. It was thus allowable to load the transformer up to its full rated capacity with lamps and instruments. Since the ratio of transformation of a small lighting transformer varies some 2½ per cent. to three per cent., whether the lamps are burning or not, this practice is open to serious objection. The defect is doubly objectionable now that instruments of far greater accuracy than formerly are made. The absurdity of producing instruments accurate within one per cent., when the error is to be increased to three per cent. or more by using them in connection with a transformer with a variable ratio of transformation, is quite obvious. Potential transformers are not of sufficient output to load with lights, and they give the correct ratio of transformation at their rated output instead of at no load, as is the case with all other transformers. The rating assigned them is 10 watts, which is ample to supply one General Electric inclined-coil voltmeter and one single-phase recording wattmeter. They can be safely loaded to 50 or 60 watts for a few minutes and are thus adapted to furnish current to phasing lamps, in circuit long enough to synchronize the machines to which they are connected.

To meet various conditions the General Electric company has designed five different potential transformers. The first (Fig. 1), wound for 1,040 volts primary and 52 volts secondary for frequencies 60 to 125 cycles, is intended for use on circuits the voltage of which does not exceed 1,250 volts, to supply current to indicating voltmeters reading to 75 volts and to primary recording wattmeters.

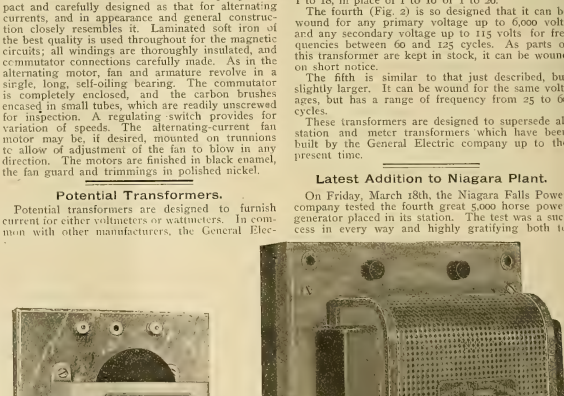
The second, wound for 1,040 or 2,080 volts primary and 52 or 104 volts secondary for frequencies of 60 to 125 cycles, furnishes current for indicating voltmeters reading to 75 or 150 volts, and is so wound that coupling the coils differently for use on different voltages is unnecessary. It has ample carrying capacity in the winding to give its full output on the lower voltages when only one-half of the winding is in use. Three primary and three secondary terminals are provided. If the transformer is used on 2,080-volt circuits the two outside primary terminals are connected to the lines. If, however, it is used on 1,040-volt circuits, the middle terminal and either outside terminal are connected to the line. By making similar connections on the secondary side either 52 or 104 volts can be obtained.

The third, wound either for 1,040 or 2,080 volts primary and 57½ or 115 volts secondary for frequencies of 60 to 125 cycles, is identical in its construction and use with the second, except that it is wound for stations using a ratio of transformation of 1 to 9 or 1 to 18, in place of 1 to 10 or 1 to 20.

The fourth (Fig. 2) is so designed that it can be wound for any primary voltage up to 6,000 volts and any secondary voltage up to 115 volts for frequencies between 60 and 125 cycles. As parts of this transformer are kept in stock, it can be wound on short notice.

The fifth is similar to that just described, but slightly larger. It can be wound for the same voltages, but has a range of frequency from 25 to 60 cycles.

These transformers are designed to supersede all station and meter transformers which have been built by the General Electric company up to the present time.



FIGS. 1 AND 2. POTENTIAL TRANSFORMERS.

Latest Addition to Niagara Plant.

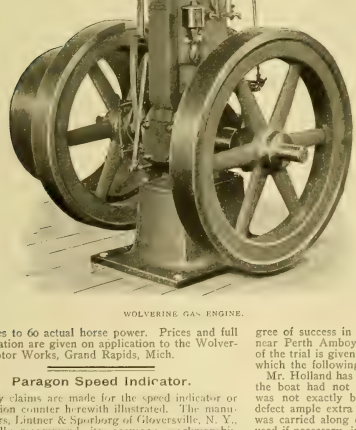
On Friday, March 18th, the Niagara Falls Power company tested the fourth great 5,000 horse power generator placed in its station. The test was a success in every way and highly gratifying both to the power company and to the Westinghouse Electric and Manufacturing company, the maker of the dynamo. This brings the capacity of the station up to 20,000 electrical horse power, and is the first of the new dynamos to be installed and operated. Additional dynamos of the same design, make and size will be installed in the power house, until the total output of electric current reaches 50,000 horse power.

K. & W. Hanger-board.

Illustrated herewith is the K. & W. hanger-board and absolute cut-out combined, which is manufactured by the K. & W. company, Pittsfield, Mass. The board has been designed to meet the various requirements occasioned by the different types and makes of arc lamps. The base is of slate, japanned black, and is made solid or with an oval hole in the center large enough to pass the stack of a single or double-carbon lamp. The methods of lamp suspension are simple and are suitable for lamps with terminals close together or wide apart, or for lamps supported by a single eye at the center. The hanger-board is also well adapted for attaching to lamp hoods. The slide-rod is actuated by an insulated handle controlled by a spring, which throws the handle either side of the center. The handle is drilled for the insertion of a cord for operating it at a distance. It can also be operated by hand or with a pole. The contacts are of phosphor bronze and all parts are dipped or polished and lacquered, making a board of handsome appearance. The operation of the slide-rod is first to shunt the lamp and then cut it in or out entirely, and absolutely without sparking. The reception the board has met bears evidence of the high grade of workmanship for which all the products of this progressive company are noted.

Wolverine Gas Engine.

The accompanying illustration represents a six horse power Wolverine stationary engine, especially designed for electric-lighting purposes and for all other purposes where a steady power is required. For several years electrical engineers have been on the lookout for a good gasoline or gas engine for driving dynamos, and the Wolverine has been brought out to meet their requirements. The trouble with the ordinary gas engine of the four-cycle type has been in the unsteadiness of operation, producing a pulsating light. To overcome this unsteadiness in operation, it was necessary to use countershafting, with a heavy balance wheel. The Wolverine engine has an impulse at every revolution, runs at high speed, and has two heavy fly-wheels, which entirely overcome the unsteadiness of operation common to other forms of gas engines. The governor on this engine is very sensitive, and operates on the inlet valve which admits gas into the upper end of cylinder. The quantity of the gas is varied as the load on engine increases or decreases, the quality of the mixture of gas remaining constant. The manufacturers of these engines guarantee them to produce a steady light without any perceptible pulsation, when belted direct to the dynamo, without the use of any intermediate countershafting. The consumption of gasoline is said to be one-tenth of one gallon per hour per actual horse power. The Wolverine engines are built in all sizes to 60 actual horse power. Prices and full information are given on application to the Wolverine Motor Works, Grand Rapids, Mich.

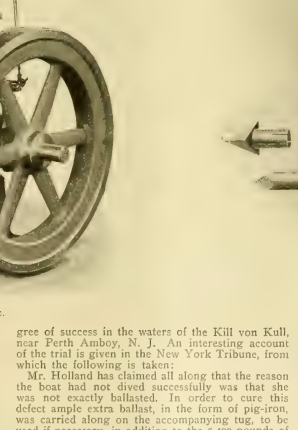


WOLVERINE GAS ENGINE.

Paragon Speed Indicator.

Many claims are made for the speed indicator or revolution counter herewith illustrated. The manufacturers, Lintner & Sporborg of Gloversville, N. Y., especially recommend its accuracy, workmanship and durability. These advantages are as cited:

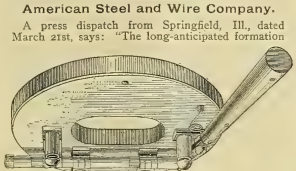
The indicator registers continuously from 0 to 5,000 revolutions per minute and then goes on and repeats, but if continuous counting is not required the register is easily and instantly turned to zero for a fresh start. It has a pistol-form grasp by which the contact is made, and a trigger-form lever for starting the registering dial, just the form of mechanical appliance to secure accuracy at starting and stopping. The spindle of this instrument may be placed in position and may be running all right, but no count will be made until the trigger is pulled. It is provided with ball bearings, to take up the end-thrust friction. The latter disappears as a defect, and overcomes the liability of slipping at the contact point and making an incorrect record. It is also provided with worm gears to actuate the dial. No matter in which direction the spindle turns, the recording dial always turns and counts in one direction, so that its recordings do not have to be read backward. The indicator is packed in a leather plush-lined case, with compartment for extra contact points, tools, etc. The cover when closed is secured with ball and socket fasteners. The case is 6½ inches long, 3½ inches wide and 1¾ inches deep. Its weight, including indicator and equipment, is 14 ounces.



PARAGON SPEED INDICATOR.

American Steel and Wire Company.

A press dispatch from Springfield, Ill., dated March 21st, says: "The long-anticipated formation



K. & W. HANGER BOARD.

of the gigantic wire and steel trust was completed this morning by the secretary of state granting license for the incorporation of the American Steel and Wire company, with principal offices located at Chicago. The object given for the organization is 'manufacturing and mining and all business relating thereto.' The capital stock is placed at $24,000,000, the largest capitalized company in the West. The incorporators are John W. Gates, Isaac L. Ellwood and Ethelbert H. Gary. The life of the corporation is given at 99 years. The fee for the incorporation was $24,500, the largest single fee ever received for an organized company in the West."

Successful Trial of the Holland Submarine Boat.

On March 17th the submarine boat designed by John P. Holland was tested with a considerable degree of success in the waters of the Kill von Kull, near Perth Amboy, N. J. An interesting account of the trial is given in the New York Tribune, from which the following is taken:

Mr. Holland has claimed all along that the reason the boat had not dived successfully was that she was not exactly ballasted. In order to cure this defect ample extra ballast, in the form of pig-iron, was carried along on the accompanying tug, to be used if necessary, in addition to the 5,400 pounds of ballast which the boat already carried.

The first attempt of the boat to dive was hardly to be called a success. Slowly her bow sank and her stern rose until the torpedo tube at her stern showed clear, while her propeller, partially in the air, was churning the water into foam. She then ran in semi-circles for some little distance, but could not force her nose deeper than the conning tower into the water.

Mr. Holland finally gave it up, and signaled to the tug for more ballast. Two hundred pounds of ballast was accordingly added. But the desired result was not secured. Two hundred and fifty pounds more of pig-iron was then stowed away, and off she went again. This time the Holland went all but under, only the top of her conning tower and her flagposts showing.

After further addition, together with some slight shifting of the ballast already in the boat, the Holland started off. Suddenly she dived and simultaneously the tug's whistle shrieked and every one on the tug burst into cheers, for the boat wholly disappeared save her flagstaffs, and from the position of these at least 2½ feet of water must have flowed over her conning tower and six feet over her hull.

After covering some 250 yards under the water, the Holland came again to the surface and after a short run made another dive. This time Mr. Holland sent her underneath the water for more than a quarter of a mile at good speed, and again coming up she gave three blasts of her impertinent little whistle to signify that the day's experiment was over.

As the tug drew alongside, the cover of the conning tower was thrown back, and the smiling, satisfied face of the inventor appeared. Mr. Holland climbed on the deck of his boat and informed the captain that he wanted to be towed back to the wharf, as the electric batteries were weak. This evidently exasperated the electrician, for his angry face appeared above the turret, as he asked: "And is it like a lame duck yez want to go back after such a performance as that?"

"Do you think she can run back under her own power?" mildly queried Mr. Holland.

"Run back under her own power!" shouted the electrician. "Sure, she could run to Jerusalem." And back she accordingly went without the aid of the tug.

The Holland is the second type of this particular boat to be built by Mr. Holland. The other one, called the Plunger, is now being built under contract with the government at Baltimore. Mr. Holland determined to build this boat because he did not like, and thought he could improve upon some of the specifications insisted upon by the Navy Department.

The boat is 45 feet in length, with a diameter of eight feet. She tapers away greatly toward the stern, where a torpedo-tube is located just above the propeller. Another torpedo-tube is in her bow. She also carries two dynamite guns capable of throwing a projectile upward of a mile. These guns are on pivots at the bow and stern.

Her superstructure is cigar-shaped, and about 25 feet long, with her conning tower some 2½ feet high, located just forward of the center. The turret also has cutwaters fore and aft to relieve the water pressures when the vessel is running awash. The boat is designed to run for at least 50 miles under water, and to be able to descend to a depth of 40 feet. In copper cylinders sufficient air is carried to supply her crew for at least six hours, and should it be necessary for her to remain under for a longer time a rubber tube on a float has been designed to give her connection with the surface and through which her air supply can be renewed. On the surface she is run by a gasoline engine, while below the motive power is electricity, with storage batteries of sufficient power to drive her 50 miles without renewing.

The method of sinking her is by admission of water ballast into various compartments on her sides, and, on wishing to rise, the water in its turn is expelled by compressed air. This, together with her diving rudders on the sides, enables her to disappear when going at full speed.

Telephotos in Naval Service.

Whatever may be the true reason, the present strained relations between this country and Spain are credited with hastening the equipment of United States naval vessels with a new signaling system.

The apparatus of the Telephotos company of Buffalo has been approved by the United States Navy Department and the company has received orders for several sets to fit out American warships. The telephotos is considered the most rapid, most powerful and effective night-signal system yet invented. It is the conception of C. V. Boughton, who is the general manager of the company manufacturing the apparatus. In its operation the electric current plays a leading part, rendering it thoroughly effective and brilliant on the darkest nights. The orders which the company is now filling were received after a severe trial on board several vessels equipped for experimental purposes. The tests were highly satisfactory, fully confirming the excellent impression created by previous tests, and now the Navy Department has decided, it is understood, to equip all United States warships with the system.

The telephotos consists of a series of four double lanterns, lighted by powerful groups of incandescent lamps, the four double lanterns being hung vertically on strong wire cables, the upper end of which can be run up to a mast or yardarm, while the lower end is intended to be fastened to the deck of the vessel. The upper half of each lamp is white and has within it a group of three lamps surrounded by powerful magnifying lenses. The lower half is red and has four lamps, in order to make the red beams the stronger, which are surrounded by heavy red lenses. The carefully insulated cable connects the lamps and passes from the lower end to the deck or the bridge, where a keyboard enables the operator to spell out the code signals about as rapidly as a typewriter is manipulated, and very much in the same manner. The keyboard is arranged on a standard and enclosed like a binnacle, the operator standing in front of it while manipulating the keys. By a simple automatic arrangement, each key as depressed lights a combination of the four red and the four white lights, making a letter or a number according to the code of signals. All of these operations are automatic and the combination is made by one touch of the key. Another feature of the keyboard is that when one letter is down all the other keys are locked so that another cannot be accidentally pushed down and confuse the signals. Any key pressed down can be turned one-quarter way round, like a screw, which motion locks it in place and leaves the signal burning in case it is desired to use it as a standing signal or order in the secret naval code. Thus the keyboard can be used to telegraph ordinary instructions by the usual letters, to send a cipher dispatch or special-code orders. Notwithstanding all this apparent complication, the keyboard and contact and its mechanism so simple that it cannot be readily disturbed or gotten out of order.

It is claimed that the telephotos has created a good impression in the British navy, and that a number of sets have been ordered for the finest English vessels.

Activity in the Copper Market.

Writing to the Chicago Times-Herald, a Houghton, Mich., correspondent states that while the talk of war has been felt to some extent in the market for mining shares, it has by no means injuriously affected activity in actual mining. With copper selling at better than 12 cents, a war would be more likely to raise than depress prices. Twelve-cent copper means annual profits of nearly or quite $7,500,000 by the mines of Houghton County. On the output of 150,000,000 pounds of refined copper, which was nearly reached in 1897 and will be exceeded in 1898, the mines of Houghton County gain 1½ net profits $1,500,000 on every increase of one cent per pound in the selling price. There is not a producing mine in the district which cannot maintain the present high wages and earn a profit on 10-cent copper. At the present time there are approximately 10,000 men employed in the mines and mills of the Lake Superior copper district at wages never exceeded. It is a matter of general comment by visitors that the Lake copper district is more prosperous than any other district in the United States, if not in the world. The activity now manifested in reopening old mines bids fair to greatly increase the number of employes and of producing mines.

A London dispatch of last Saturday states that there is extraordinary activity in the copper market, especially at Birmingham. Authorities agree that the supplies are manifestly scarce, and that the stocks are unprecedentedly low. Good brands have advanced £2 10 ton since January 1st. The activity is largely attributed to the projected expenditure of the United States for war material, and a possible rupture with the principal copper countries.

Troubles for Acetylene Promoters.

[Special dispatch to the Western Electrician.]

Niagara Falls, N. Y., March 22.—The Electrogas company has foreclosed upon the Acetylene Light, Heat and Power company.

CORRESPONDENCE.

New York Notes.

New York, March 21.—Acting on the report of the committee to which the matter was referred, the Rapid Transit Commission has passed upon the Manhattan Railway company's application for permission to make elaborate extensions to its elevated railroad system. In general, the commissioners accede to the Manhattan's requests, but with some important modifications. The company is urged to change its motive power and is given 30 days, after the preparation of the "detailed certificates" of the franchises, to accept or reject the conditions imposed for the construction and operation of the new routes. The commissioners make it evident that they have not abandoned their own tunnel-railway scheme in the following paragraph of the adopted report: "We cannot approve the suggestion made to us by the president of the Manhattan company that it be granted an underground route under the boulevard. That would imply the destruction of the real and sufficient rapid-transit plan for which the people of the city have voted, which has been repeatedly approved by practically unanimous votes of the Legislature and practically unanimous action of the city authorities, and which has now reached the stage of actual appellate division. Those routes and plans should be scrupulously observed and carried out. There is no possible room for doubt that the elevated-railroad system, however extended and improved, will in a very brief time have all the capacity it can carry. There will in addition be business more than sufficient to make profitable a modern rapid-transit road, built in accordance with the plans so universally approved. These plans represent years of labor, vast detail and a very considerable expense incurred by the city. To destroy them by surrendering an essential feature to the Manhattan company would be a deliberate and serious sacrifice of the future interests of the city."

It is expected that electric cars will be running in upper Eighth avenue this week. These cars will start at One-hundred-and-fifty-fifth street and run to Fifty-ninth street, where they will turn east. At Lexington avenue they will be switched back. Part of the Second avenue line will be equipped with electricity this spring.

The Kings County Electric company, which is rushing work on its plant at the end of Gold street in Brooklyn, in order to start operations by early summer, has contracted to furnish almost its entire capacity of more than 20,000 horse power before the engines have turned a single revolution. The directors of the company, it is asserted, are considering the feasibility of buying more ground and extending the plant at an early day. "The increase in the use of electricity," said one of the directors of the company to a Tribune reporter recently, "is one of the most remarkable tendencies of the present day. So far as I am able to learn, not much of the business we have secured has come from existing companies. It is nearly all new. The use of electricity is only in its infancy in Brooklyn. It is the coming power that manufacturers will and is sure to use, not steam in a few years. The Worthington Pump Works in South Brooklyn have taken the initiative in discarding steam for electricity, and by this example will be followed in a few months by a number of establishments whose owners are 'keeping tab' on the results obtained by the Worthingtons. The change is taking place so gradually that it attracts far less attention than it deserves. It is a process of evolution marking a passage from a lower to a higher industrial development."

Part of the $50,000,000 appropriated by Congress as a national defense fund will go to electrical manufacturers. In a few days bids will be solicited for placing telegraph cables to connect Governor's Island with Sandy Hook, Fort Wadsworth and Fort Hamilton, and for running private land telegraph lines between Willets Point, Fort Schuyler and Fort Slocum, with connections to Governor's Island.

The Consolidated Electrical Conduit company of this city, which holds the right to equip the canals of the state with appliances to propel boats by means of electricity, has filed in the office of secretary of state a certificate of continuance of its corporate existence for five years, from November 3, 1898. The company was originally incorporated in 1893, for a period of five years. The certificate is attested by Frank W. Hawley, Charlton T. Lewis, William Mertens, C. P. Wedder, J. S. Bache, Charles Ambrecht and Peter F. Meyer. M. S.

PERSONAL.

President Insull of the National Electric Light association says that great interest is shown throughout the East in the forthcoming convention of the association in Chicago. Mr. Insull returned to Chicago on Monday after a two days' eastern trip.

Colonel John C. Van Dozer, an old-time telegrapher, is dead. During the war he was superintendent of military telegraphs at Nashville and a member of the staff of General Rosecrans, who died this month. Col. Van Dozer died in Escanaba, Mich.

J. H. Hallberg, electrician of the Standard Thermometer and Electric company of Peabody, Mass., after three weeks' stay in Chicago, has left for the East, returning to Massachusetts by way of Cincinnati, Pittsburg and New York. Mr. Hallberg's new series lamp with enclosed arc has attracted much attention.

Frank B. Rae has been retained as consulting engineer by the Crane Elevator company and the Calumet Electric Street Railway company. The latter is owned by the National Bank of Illinois, which is in the hands of Gen. John McNulta, receiver. Mr. Rae is also overhauling the steam plant of the Ludowici Roofing Tile company at Chicago Heights.

Louis A. Ferguson, general superintendent of the Chicago Edison company, has returned from a five weeks' visit to England, France and Switzerland. Mr. Ferguson corroborates the stories that have been received from all visitors to England that there is great activity in electrical work. He says that Americans are taking advantage of the "boom" and that they are leading in all the great undertakings.

Mr. R. McRae, electrician and expert for the Electric Storage Battery company of Philadelphia, is in Chicago engaged in the important work of installing the large storage battery that is to assist in carrying the load of the Chicago Edison company's system. Mr. McRae is one of the oldest and most experienced storage-battery experts in this country. He studied under Sir William Thomson (now Lord Kelvin) in England, and has held various important positions since coming to this country, about 15 years ago. It is safe to say that this important installation could not have fallen into better hands. Mr. McRae has recently been doing most excellent work for the company in Pittsburg, where a large battery has been placed in position to act as an auxiliary source of supply to one of the Pittsburg street-railway companies.

Many friends will regret the announcement of the decease of Mr. Jules Viennot of Philadelphia, which occurred at his late residence, 4424 Chestnut street, on March 11th, after a brief illness. Mr. Viennot was 72 years of age and had for the last 15 years conducted one of the largest advertising agencies in the country. His special efforts were centered in the mechanical trade, and by his strict integrity and upright dealings he built up a business which has among its clients some of the largest manufacturers in the country. Mr. Viennot was universally respected by all with whom he came in contact, and his kind consideration and help will be long remembered by many newspaper representatives with whom he did business. He was born in Paris, and came to this country 50 years ago. He was a member of the Franklin Institute and of the French Benevolent association. Some two years ago the honor of being an Officier De L'Academie was bestowed upon him by the French government. The business will be conducted by his estate, under the management of Mr. J. A. Thompson, a gentleman who has been connected with Mr. Viennot many years. He is fully capable of caring for the business, after the long training he has had.

ELECTRIC LIGHTING.

Irving & Hackaday have purchased the electric-light plant at Itasca, Texas.

Blake Dupree, receiver of the Citizens' Electric Light and Power company of Galveston, Texas, has applied for permission to issue receiver's certificates for $20,000, to be expended in improvements to the plant.

The Winnsboro (S. C.) Electric Light and Power company will erect a plant for 750 incandescent lamps, costing about $3,000. A water-works system will probably be constructed later on. R. G. Andrews is president of the company.

The Chicago, Rock Island and Pacific Railroad company has decided to equip all engines which haul important passenger trains at night with electric headlights, but the ordinary headlights will not yet be discarded on all passenger engines.

The Mutual Light and Power company and the Montgomery Light company of Montgomery, Ala., have consolidated and reorganized, electing W. F. Vandiver, president; C. G. Armstrong, vice-president, and B. S. Maultsby, secretary. The company will expend about $150,000 in improvements, which will include new gas plant, two new boilers, a 1,000 horse power engine, etc.

The Boston and Albany Railroad company is experimenting with the car-axle system of train lighting. A dynamo is mounted on one of the axles and operated by gearing. The current generated goes directly to the lamps or to a storage battery if the lamps are not in use. An automatic cut-out disconnects the dynamo from the battery when the speed falls below a certain amount—variable at pleasure—so that the batteries cannot discharge through the dynamo. When the train is standing at a station or elsewhere, the lights are maintained by the batteries, which are of sufficient size to keep them burning for 10 hours. Nineteen lamps are in the body of the car, and one over each platform. A pole-changing device maintains the correct polar-

ity of the current through the batteries when the car runs in the reverse direction. An officer of the railroad company says that no extended trial of the appliances has yet been made, and only one such car is as yet in use, but it gives a good light, and thus far works pretty well.

The following bids were received by the United States engineer at New London, Conn., for electric lighting and power installation at Great Gull Island, New York: McKay Howard Engineering company, Baltimore, Md., entire plant, $5,290 (recommended for acceptance); Randall P. Barron, New York, N. Y., electrical apparatus, $3,285; Westinghouse, Church, Kerr & Co., New York, engine, $2,100, $2,200 and $3,068; De La Vergne Refrigerating company, New York, engine, $2,410; Sprague Electric company, New York, electrical apparatus, $2,941.50; New Jersey Foundry and Machine company, New York, electrical apparatus, $3,000.

ELECTRIC RAILWAYS.

The Flushing and South Shore Railroad company has been incorporated with a capital of $150,600 to build 15 miles of road in Queens county, New York.

The Brooklyn Avenue Railway company of Kansas City, it is stated, will change its motive power to electricity. This company operates about seven miles of track.

The Buffalo, Hamburg and Aurora Railway company will open the bids for the construction of its 19½-mile line and the power plant and rolling stock on March 30th at its office in Buffalo.

The Wellston and Jackson Railway company has made application to the City Council of Jackson, O., for a franchise to build an electric railroad and to furnish lights to the city. M. S. Connors is interested in the company.

Work is proceeding uninterruptedly on the power house of the South Side ("Alley L") Elevated Railroad company at State and Fortieth streets, Chicago, and it is expected that current will be sent out on the line by the middle of next month. The greater part of the cars are electrically equipped with the Sprague system.

Three new trolley lines are under contemplation in the vicinity of Allentown, Pa. A line from Allentown to Emaus, six miles long, is to be begun on April 1st. New York capitalists intend to complete the Allentown and Kutztown road of 18 miles, and the Lehigh Valley Traction line will be extended four miles to Coplay and Egypt.

The city electrician of Liverpool, England, has prepared a plan for an important addition to the city electric-lighting system, with the view to providing the current necessary for working and lighting the street cars of the city. A large new generating station is to be established on a site near the Leeds and Liverpool Canal, at a cost of about $750,000. Liverpool will thus have a combined lighting and traction plant.

A Baltimore press dispatch, dated March 13th, states that for the last week or 10 days M. Soulecroup, assistant superintendent of the motive power of the Paris, and a corps of five assistants, have been inspecting the electrical plant of the Baltimore and Ohio railroad. The splendid work being done by the electric motors in the Belt Line Tunnel has attracted attention all through Europe, and M. Soulecroup's visit to this country was for the express purpose of investigating the ways and means of operation. The railroad in question is to be an underground line running from one end of Paris to the center of the city, and it is probable that it will be equipped with electric motors similar to those used on the Baltimore line, except that they will be much smaller.

At a recent meeting of the Chicago City Council a petition was presented by the Chicago Electric Transit company for an ordinance to run trolley lines in the following-named streets for a term of 50 years: In California avenue, between Elston avenue and Lawrence avenue; in Kedzie avenue, between Elston avenue and Lawrence avenue; in Central Park avenue, from Elston avenue and Lawrence avenue. A similar petition from the North Side Electric Street Railway company asked franchises for these streets for trolley cars for 50 years: In Dearborn avenue, between Kinzie and Illinois streets; in Rush street, between Dearborn avenue and Rush street; in Rush street, between Illinois and Ohio streets; in Ohio street, between Rush and St. Clair streets; in St. Clair street, between Indiana and Pearson streets. Neither petition provided for compensation to the city, and both were referred to the committees on streets and alleys.

The volume of traffic on the Metropolitan elevated road during the month of February surpassed expectations, and railroad men find difficulty in explaining the increase not only over the January average but over the December average. The passenger receipts of $93,768.75 indicate that the average number of paid fares a day was 66,942, or the largest in the history of the road. In December, with the holiday shopping, the daily average amounted to 66,600, so that February traffic established a new record, with a gain of over 300. Compared with the traffic in January the increase is 5,295 a day, or eight per cent. The increase in operating expenses to 67 per cent. of passenger earnings may seem less favorable at first sight, but the fact that the Union Loop rental, a large factor in the operating expense, is paid in the month following the period in which it was incurred complicates this question. The voucher paid to the Union Elevated Railroad company last month for January amounted to $13,369, and after deducting 10 per cent of gross receipts in January, for rental proper, the cost of power and maintenance of the loop averages $123 a day. In December the average was $111 a day, but during January power for operation of Metropolitan trains on the loop was furnished by the Union Loop power house for the first time.

TELEPHONE.

The Monroeville, Ohio, Telephone company has been operating its exchange only nine months, yet in that time it has more than doubled its list of subscribers and built 18 miles of pole lines to connect with neighboring towns, besides giving telephonic communication to farmers along the road.

The Marysville (Ohio) Telephone company contemplates the coming summer extending toll lines to nearly every town in the county. The first to be built will be a stretch of 16 miles to Richwood, taking in the villages of Broadway, Harisburg and Magnetic Springs. The line will then probably be extended to Byhalia, on to Mount Victory, where it will intersect the line of Marion, Kenton and Bellefontaine. This will make a very popular line, as almost direct connections can be made to each county seat in the four central counties in the state.

TELEGRAPH.

Apropos of the war excitement, the Telegraph Age notes that old-time war telegraphers are impressed by the fact that, for the first time since the war between the states, the War Department has ordered the use of the cipher code in transmitting dispatches to the various army posts throughout the country.

A recent session of the New Jersey State Senate was taken up in discussing Senator Reed's bill providing that when a telegraph company refuses to pay local taxes assessed upon its poles and wires the latter may be seized and sold. Senator Reed said the present law is such that while the poles and wires may be sold, the property cannot be touched, and the companies snap their fingers at the efforts of the local assessors to reach them. Several senators expressed fear that the bill would apply to railroads, but Mr. Reed assured them that it would not affect railroad, telephone, or electric-light companies. It passed by a vote of 11 to 7.

ELECTRICAL SECURITIES.

The Citizens' Electric Light and Power company of St. Louis has increased its capital stock from $1,500,000 to $2,000,000.

The Metropolitan Street Railway company of New York has declared a quarterly dividend of 1¼ per cent, payable April 15th.

The statement of the Electric Storage Battery company for the year ended December 31, 1897, shows a profit over all operating expenses of $325,290.92. Income from royalties and investments make total net profits of $340,008.99. After deducting interest on bonds the net earnings of the company for the year were $321,808.99. The net surplus was $257,744.42.

The Edison Electric Illuminating company of New York reports gross earnings for February of $256,880, an increase of $4,076, as compared with the same month of last year, and net $134,573, an increase of $16,565. For the two months ended February 28th the gross earnings were $555,188, an increase of $102,085, as compared with the corresponding period of last year, and net $299,962, an increase of $45,411.

A proposition is to be submitted to the stockholders of the Consolidated Traction company of New Jersey on March 28th for the leasing of the company to the North New Jersey Traction company, the latter being a new corporation which has been formed to control many of the surface lines in the northern section of New Jersey. Consolidated New Jersey, which is to be guaranteed a rental on a sliding scale beginning with two per cent. for the first year, earned about 2¼ per cent. on its stock in 1897.

The $5,000,000 capital stock of the Union Elevated Railroad company was placed on the regular list of the Chicago stock exchange last week. This action places all the securities based upon the Union Loop property on the exchange, the $5,000,000 bonds having been listed previously. In the statement to the governing committee the amount of bonds outstanding was put at $4,200,000, indicating that the recent sale of $712,000 by Mr. Yerkes in the East reduced the $1,050,000 generally supposed to be in the hands of the trustee under the mortgage, as a reserve against judgments for damages, to $800,000

MISCELLANEOUS.

The next meeting of the Engineering Association of the South will be held in Nashville, Tenn., on April 14th.

The Self-propelled Traffic association has arranged for trials of heavy-traffic motor vehicles to come off in Liverpool during May next. The Auto-mobile club of France has been invited to send delegates, and it is expected that the prominent officials and members of this club will witness the trials to be given on that occasion.

An ingenious advertisement is being worked in Philadelphia's streets at night. A man drops a lot of small change on the sidewalk and, of course, everybody looks in his direction. Directly after the money is dropped the man presses a button on his coat and there appears in his hat a transparency with electric lights showing the name of a certain play. All the coins have a hole in them through which is fastened a stout thread, and a single jerk of the man's hand recovers every piece.

Consul Jackson at Cognac, France, has reported to the State Department at Washington that the city of Niort proposes to have electric railways and lights for its streets. Manufacturers interested in this subject can obtain information by addressing Monsieur le Maire de la Ville de Niort, Deux-Sevres, France. The consul says there is also a movement on foot to establish a tramway, with the new port, La Pallice, by an electric line 2½ miles long. Communications in regard to the matter should be addressed to Monsieur P. W. Morch, Chamber de Commerce, La Rochelle, France.

The Navy Department, through the bureau of supplies and accounts, is inviting sealed proposals until April 5th for furnishing the Norfolk, Va., navy yard 1,000 electric lamps of 16 candle power; 800 Edison lamps, 32 candle power; 60 pounds fuse wire, 1 to 30 amperes; 50 pounds solder; 10 bottles Yager's soldering scales; 400 pieces cut sheet mica; 400 hard vulcanized fiber washers; 100 Edison fuse plugs; 20 midget two-wire cut-outs, and other supplies. Blank proposals can be obtained upon application to Edwin Stewart, paymaster-general, United States Navy, Washington, D. C.

TRADE NEWS.

The Navy Department has placed a large "rush" order for enclosed arc lamps with the Jandus Electric company of Cleveland.

J. S. Petersen and O. F. Fobes have formed a copartnership to engage in the electrical construction and supply business at Appleton, Wis., under the firm name of Petersen & Fobes.

A very interesting pamphlet devoted to the properties and product of the Illinois Steel company of Chicago has just been issued for distribution. It contains much information of a general character, as well as descriptions of the several departments of the business.

The Western Electric company's fan catalogue for 1898 is an excellent piece of work. Desk and ceiling fan motors for both alternating and direct current are described. The illustrations are very satisfactory. Some of them are full-page, and they supplement the text admirably.

The Michigan Pipe company of Bay City, Mich., is working on an order of 14,685 creosoted tamarack cross-ties for the Denver Consolidated Tramway company. The Denver Consolidated Tramway company purchased 1,600 creosoted ties from the Michigan Pipe company last year, and, after investigating the merits of creosoted ties, has placed this large order for its 1898 improvements.

The Rae Motocycle company of Chicago has been incorporated with a capital stock of $40,000. The officers are: President, Hugh L. Burnham; vice-president, F. B. Rae; secretary, Paul Synnestvedt; treasurer, C. W. Dickerson. The company will manufacture electrically propelled vehicles under Mr. Rae's patents, building the motors and batteries. The Sterling Cycle Works is under contract to build the first equipment—a cab—for the Rae company, and the latter expects to be soon in the market for businesss.

General Sales Agent L. F. Frorup of the Schiff-Jordan company of New York is now taking an extended tour in the eastern and western states, and reports that he finds business of all lines very good, especially the sale of the Ship carbon, the excellence of which for arc lighting is well known to all branches of the electrical trade. Mr. Frorup reports having received contracts for 180,000 of this high grade carbon one day last week. He is an old resident of Chicago, and his hustling abilities have been shown in connection with the Schiff-Jordan company.

Mr. Paul G. Fiedler of Yokohama, Japan, has turned to that country after several weeks' business visit in the United States. Among the agencies which he has secured are those of the S. M. Morgan Smith company of York, Pa., Fort Wayne Electric corporation, Queen & Co. and Chicago Fuse Wire company. In addition, Mr. Fiedler is the principal represen-

ative in Japan of the Jandus Electric company and the Buckeye Electric company of Cleveland, Ohio. Mr. Fiedler is well remembered in the electrical trade as a manufacturer of silk filaments for incandescent lamps in Boston, Mass., in which he was prominently identified until about two years ago. He reports a very successful business thus far and the outlook for the future as exceedingly bright. His many friends will be pleased to hear of his success.

Mr. Edward B. Hatch has been elected president and general manager of the Johns-Pratt company of Hartford, Conn., to succeed the late president, Mr. H. W. Johns. The selection of Mr. Hatch is directly in line with the usual policy of this company in recognizing the ability of its employes. Mr. Hatch has been identified with the concern for over 13 years, beginning at the foot of the ladder, and by diligent work and application he has won the confidence of its stockholders, and has been general manager for some time. He has an extensive acquaintance in all branches of the electrical trade, and his friends will wish him continued success at the head of this large concern. Mr. H. H. Luscomb, who has been elected secretary of the Johns-Pratt company, has been in its employment several years. Vulcabeston, the product which is manufactured by the Johns-Pratt company, is the well-known insulating material.

BUSINESS.

The Hawkeye Telephone Construction company of Des Moines and Chicago has a "local and long-distance telephone" sign which has been indorsed by the Iowa Telephone association. The sign is 17 inches square and is made of enameled iron, the design being in the shape of a Maltese cross.

The Joseph Dixon Crucible company's circular on "Friction and Lubrication" is a carefully prepared essay on the subject. It shows the value of graphite in a convincing manner. Samples of graphite and information are sent to users of lubricants without charge by the company, which is addressed at Jersey City, N. J.

M. H. Reagan, the incandescent-lamp repairer of 178 Green street, Jamaica Plain, Boston, calls attention to the fact that he is operating under a license granted by the lamp manufacturers' association, and thus has full use of the patents controlled by the pool. He guarantees improved methods and satisfactory results.

The tried and reliable P. & B. insulating products of the Standard Paint company of New York are reported to be in greater demand than ever. These goods—the insulating compound, insulating tape, armature and field-coil varnish and ruberoid motor cloth—have stood the test of years with credit, and deserve their success.

The demand for a dynamo brush which can meet the requirements of engineers has been one of the problems in the electrical trade, and it would seem, from reports, that the K. & W. company of Pittsfield, Mass., has overcome the difficulties in this regard. This company reports that its business in this department has increased greatly during the last two months, and it shows a large number of letters from prominent users, who speak in the highest terms of the K. & W. dynamo brush. It is also pleased with the flattering demand for its Hardy incandescent lamp, which is proving very popular with the trade where sustained candle power is considered.

The Davis & Egan Machine Tool company of Cincinnati, Ohio, reports that its already large foreign business is steadily increasing. It received last week, through its store at London, England, orders from C. & D. Peters & Co., at Moorgate, England, for a number of heavy screw machines and milling machines; also a large duplicate order from Fraser & Chalmers of Erith, England, consisting of engine lathes, chucking lathes, radial drills and boring mills. Through the company's office at Berlin, Germany, it received an order from a concern at Stettin, Germany, for an outfit of bicycle machinery, including hub machines, screw machines, pedal machines and sprocket milling machines.

The E. W. Bliss company, the well-known manufacturer of presses, dies and special machinery, of Brooklyn, N. Y., reports an unusually large demand for tools of its manufacture, especially those adapted for electrical work. For this purpose the company manufactures a large line of machines for blanking and notching armature core disks and sections, as well as for making other parts of electrical machines. Included in this list is a very large number of double-crank presses, from the smallest up to the largest size. In connection with electrical work the Bliss company calls special attention to its improved automatic notching press for disks of all diameters. Those who have used this machine declare it to be the best tool on the market for its specific work, and the manufacturers will be pleased to correspond with those who are interested regarding it.

The Western Electric company invites attention to the Lakon transformer, the Star soldering stick and the Simplex friction tape. A sample of the tape will be sent free of expense to anyone interested. Writing of the transformers, the Missouri Valley Electric Light company states that it has had a number of them in circuit for two years, and that they have given excellent service. The manufacturers of the Lakon transformers are pioneers in their trade. They have recently completed a large three-story brick factory, which is equipped with the best facilities to enable them to manufacture transformers to the best possible advantage. Their laboratory is most complete, being fitted up with a full complement of instruments with which to make exhaustive transformer tests, and thus they are assured of the quality of the transformers before they are shipped to purchasers.

The Mica Insulator company, whose offices are at New York and Chicago, with a branch at London, England, recently received from one of the large builders of electrical machinery orders for over 5,000 Micanite segments of a large pattern (many of the segments being more than 17 inches in length), and from another leading manufacturer of electrical apparatus an order for 2,000 segments; also from one of the leading motor builders an order for 26,000 segments. This volume of business would indicate that the company's Micanite segments are meeting with favor among machinery builders. The company claims that its segments are softer and wear down more evenly than mica segments. Therefore they are said to give better satisfaction. A sample set of segments for any one of the smaller machines will be furnished free of expense to electrical manufacturers or repair concerns which are desirous of demonstrating the value of the segments.

The Clonbrock Steam Boiler company of Brooklyn, N. Y., recently closed an order for boilers of 500 horse power capacity for the Coney Island and Brooklyn Railroad company. These will be installed at the station located at Smith and Ninth streets, Brooklyn, and will make a total of 2,300 horse power of the Morrin Climax boilers at this location. The Clonbrock company has also received an order from the same company for 500 horse power to be located at the DeKalb avenue station, where it has already 2,100 horse power in operation. These orders were in the open market for some time, and, after close investigation into the merits of the various boilers which were offered, the order was given to the Clonbrock company. The L. Candee company of New Haven has placed an order for 1,000 horse power with the Clonbrock Steam Boiler company, for immediate delivery. General Manager S. V. Morrin reports that his company is enjoying a large business, and that the prospects in its line of trade are exceedingly bright, as it has more prospective work ahead at present than it has had for many months. The Climax boiler has a national reputation, and is nowhere better known than in the electrical and street-railway fields. The economy with which this boiler can be run, and especially in places where small space can be utilized, presents a strong argument in its favor. The Clonbrock company has recently issued a new catalogue which is full of interesting information about boilers.

ILLUSTRATED ELECTRICAL PATENT RECORD.

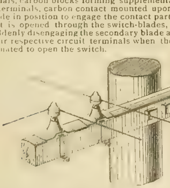
Issued March 15, 1898

600,509. Controller for Electrically Propelled Vehicles. Reginald T. D. Brougham and Walter C. Bersey, London, England. Application filed December 13, 1897.

Connection is established between the foot and switch levers so that the first movement of the former causes a rapid and wide separation of the contacts, and another connection between the foot-lever and brake-lever enables the movement of the former gradually to operate the latter

600,523. Quick-break Electric Switch. Thomas E. Drohan, Chicago, Ill. Application filed November 13, 1897.

A main and a secondary contact blade are pivotally mounted and adapted to close the circuit between the terminals, carbon blocks forming supplemental contact parts or terminals, carbon contact mounted upon the secondary blade in position to engage the contact parts after the circuit is opened through the switch-blades, and means for suddenly disengaging the secondary blade and contact from their respective circuit terminals when the main blade is actuated to open the switch.



NO. 600,607.

600,527. Depressible-rail System for Electric Railways. William Grunow, Jr., Bridgeport, Conn. Application filed April 12, 1897.

An electrical contact system consisting of contact receptacles having a tubular projection formed in the cover thereof and being provided with a mercury receiver, connections between the receiver and source of electrical supply, a sleeve movably mounted in the tubular projection and having outwardly directed arms, springs supporting the arms, a contact device carried by the sleeve and a depressible rail connected with the contact device.

600,607. Insulator Support for Electrical Conductors. Fred Benedict, Niles, Mich. Application filed September 13, 1897.

An arm is employed for suspending an electrical conductor, a strap to embrace the support and means for clamping the strap thereto, a bolt carried by the strap and an insulator carried by the bolt.

600,616. Alternating-current Meter. Georg Hummel, Munich, Germany. Application filed October 30, 1897. Patented in Hungary December 13, 1895; in Switzerland January 2, 1896; in England January 8, 1896; in Italy February 17, 1896; in France April 20, 1896; in Spain April 26, 1896, and in Austria July 10, 1896.

This is an alternating-current meter of the motor type, in which the combination of an auxiliarly wound electro-magnetic core of a general U or horseshoe shape is combined with main windings laid in grooves or holes, in the electro-magnetic core, means whereby the proper phase displacements may be obtained, and a moving part under the influence of the electro-magnetic core for indicating the passage of current through the windings.

600,633. Trolley. John Clayton, Cuyahoga Falls, Ohio. Application filed November 4, 1896.

The head sections are adapted for connection to the trolley pole; hollow bearing sections are connected to the head sections and adapted to contain the lubricant and extending inwardly, having their inner edges meeting, each bearing section being provided with a lubricating opening, and a trolley wheel mounted to turn on the bearing sections.

600,693. Method of Making Soluble Metal Electrodes for Accumulators. Jules Julien, Brussels, Belgium. Application filed September 26, 1896. Patented in Belgium March 10, 1896; in Germany March 18, 1896; in France April 1, 1896; in England April 2, 1896; in Austria April 25, 1896, and in Hungary April 27, 1896.

The process of producing a soluble electrode for use in secondary batteries consists in depositing on a copper plate, by electrolysis a finely-porous surface of pure copper, then amalgamating the copper surface so produced, and finally depositing on the amalgamated surface a coating of zinc to form the active surface of the electrode.

600,719. Galvanic Battery. Emil Habermann, Michigan City, Ind. Application filed October 7, 1897.

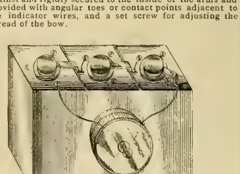
A wick is disposed between and in contact with both elements, and an exciting fluid is isolated from the elements and a portion of the wick is immersed.

600,743. Automatic Safety Circuit Closer and Cut-out. Walter L. Pratt, Adams, N. Y. Application filed May 13, 1896.

The device comprises hinged arms, carrying loop connections, the arms being held normally in circuit by a fuse wire, a plate through which the current passes, and which acts as a magnet, a pivoted armature mounted upon the plate, and a needle or pointer also pivoted upon the plate co-operating with the fuse wire.

600,765. Automatic Fire Alarm. Robert J. Baker, Baltimore, Md. Application filed April 28, 1897.

A thermostat, comprising an insulated iron bow in contact with the battery wire and having outwardly projected arms extending toward the indicator wires, parallel with the battery wires, bars of different expansibility lying against and rigidly secured to the inside of the arms and provided with angular toes or contact points adjacent to the indicator wires, and a set screw for adjusting the spread of the bow.



NO. 600,850.

600,850. Primary Battery. J. Ensign Fuller, New York, N. Y. Application filed April 5, 1897.

A battery casing is provided with vertical partitions whereby separate chambers are formed therein, and divided by transverse partition plates whereby separate cells and storage compartments are formed, the cells being closed at one end by the transverse partition plates and at the other by plates to which carbons or poles are secured, the carbons being provided with side openings and also with central openings through which are passed the zincs, and the transverse partition plates being provided with ports or passages, and means for opening and closing the same consisting of shafts which pass through the bottoms of the compartments and are provided with valves at their inner ends.

Western Electrician.

EVERY SATURDAY.

Vol. XXII. CHICAGO, APRIL 2, 1898. No. 14

Electrolytic Work at Niagara Falls.

By Orrin E. Dunlap.

The Mathieson Alkali Works at Niagara Falls occupy about the largest plot of ground on the Niagara Falls Power company's property yet leased for an electrolytic industry, and the buildings are most substantially built of brick, a fence surrounding the entire plot. Both in the front and at the rear the Niagara Junction railway affords excellent receiving and shipping facilities. This company also has a plant in Saltville, Va., and offices in New York and Providence, R. I. The president of the company is Edward E. Arnold.

The Castner electrolytic process is used to make caustic soda and bleaching powder. The raw material used is common salt, which is dissolved and fed into the cells built of slate slabs. The current enters at the carbon terminal or anode and carries the metallic sodium with it to the mercury cathode, there uniting with the mercury, and forming an amalgam. At the carbon terminal the other element of the raw material, chlorine, is liberated and drawn off by an exhauster which is driven by electricity. The cell is built to rock, and has three divisions or compartments, the outer two being similar, while the one in the center is different. The anode is formed by the amalgam and mercury, and the cathode by an iron grid. Water is supplied to this compartment the current causes it to unite with the sodium of the amalgam, thus forming sodium hydrate or caustic soda. The air carries off the liberated hydrogen. Large kettles receive the caustic liquor, and the water is disposed of by heating, leaving the caustic solid and beautifully white. Lead chambers, having their bottoms covered with layers of slacked lime about four inches deep, receive the chlorine gas, and sponge-like the lime absorbs the gas, charging it to the extent of nearly 40 per cent.

The electrical room of the Mathieson company's Niagara plant (Fig. 1) is one of the finest at the Falls. The floor is of wood, the walls are white, and the light comes from skylights. The dimensions of the room are 125 by 40 feet. Its position in the plant is to the north of the cell room. In this room are installed the static transformers, the rotaries and the switchboards. In all there are 31 rotaries, each capable of converting about 200 horse power from about 120 volts alternating to 200 volts direct current. The rotaries are placed on the south side of the room, and the static transformers and the switchboards on the north side, the installation in its entirety presenting a most attractive appearance. It converts 2,000 horse power at a voltage of 2,200 at 25 cycles to direct current having a voltage of about 200. On passing through the cell room one notices that the rows of the cells are uniform and run from north to south, being connected up in sets.

On the switchboards are mounted the instruments, controllers, field rheostats, fuse boxes and main primary switches. The controllers afford a range of 100 volts on the direct-current side of the rotaries, thus providing means for keeping the voltage proportional to the cells in use. By cutting in or out sections of the primaries of the static transformers, the controllers easily serve to vary the pressure to the rotaries. The static transformers are shown in the illustration which is presented on this page, as they are located in the rear of the switchboard. Each set of these transformers consists of two machines of 100 horse power, and reduces the voltage from 2,200, as supplied by the Niagara Falls Power company, to from about 170 to 300 volts. To the rear of the rotaries, on the south wall, are located the main switches and circuit breakers.

In addition to the electrical apparatus described the plant has 20 two-phase induction motors, which are used for various purposes, to furnish power in the machine room, drive blowers, operate pumps and cranes.

The exterior view of the plant (Fig. 2) presented on page 194 shows it from the west side. The two-story building to the left is the office building. It will be observed that the majority of the buildings are low and lighted from the top.

FIG. 1. ELECTROLYTIC WORK AT NIAGARA FALLS.—TRANSFORMER ROOM

A Flood Causes Acetylene Explosions.

A curious accident was reported from Dayton, O., last week, in which water caused a fire. The Craig-Reynolds shops in North Dayton were flooded with 10 feet of water, which reached some packages of carbide of calcium. This formed acetylene gas, causing several explosions and a fierce blaze. The Fire Department had to fight the flames from boats. The damage was $10,000.

Northwestern Electrical Association.

Official announcement has been issued by Thomas R. Mercein, secretary of the Northwestern Electrical association, that the steamer Northwest has been secured for the summer meeting of that organization. Passage can only be secured by invitation cards issued by the secretary, as it is not proposed to make this a general excursion, but retain the electrical character of the company. Mr. Mercein says:

Invitation cards are issued in the name of persons invited are not transferable, and are issued from this office only. A request for one will be considered a guarantee that the person for whom it is asked will accept it and pay his own steamer transportation to Duluth on or before May 25th; persons intending to take the trip must send their invitation card to the secretary, with check or money order for $15 for each person, drawn in favor of the association covering the steamer transportation referred to. Receipts will be sent and name forwarded to steamer committee for proper assignment of which due notice will be sent to applicant. Other modes of general information I. M. Hill, W. W. Dodd or I. L. Peaslee have been appointed a special committee without any arrangements. For general information in connection with the entertainment of the ladies' part of that committee, I. M. Hill, 164 Monadnock Block, Chicago, Illinois.

G. H. Simons contemplates putting in an electric light plant for Canby, Minn.

New York Exposition Notes.

Mr. Fred Catlin, the manager of the telegraphic tournament at the electrical exposition in New York next month, has completed the preliminary arrangements for that contest, and has arranged the classes. Circulars on the subject are ready for general distribution, and there is already a great demand for information on the subject from all parts of the country. Mr. Catlin informs the exhibition management that the entries will probably be more numerous than at any other tournament that has occurred, and thinks that some of the records will be phenomenal. It is proposed, in addition to the regular contest, to have interesting exhibits of telegraphic skill in novel directions. Mr. Jesse H. Bunnell, the electrical manufacturer and veteran operator, is taking a deep interest in the contest, and has volunteered to equip the whole stage with the necessary apparatus for the competition in the shape of keys, sounders, batteries and auxiliary appliances. Mr. Bunnell is desirous to have a separate prize offered for an "old-timers' class," and has already entered himself for that contest. He has the reputation, dating from the war, of being an unusually fast and skillful operator.

Mr. H. V. Parsell, the well-known banker of New York, who has long been interested in electric-deposition work, has kindly placed in the hands of his son, Mr. H. V. Parsell, Jr., the electrical engineer, for exhibition at Madison Square Garden during May, a marvelous collection of galvanoplastic work, done during a long series of years. It may be doubted whether any other amateur could possibly show anything approaching this remarkable collection in beauty and interest. It will not only include several striking pieces, as large as 25 inches by 25, and reproducing celebrated works of art and famous men, but will comprise large numbers of coins, medals and fac-similes of antique gems. The most extraordinary part of this beautiful collection, however, will be that which embraces the reproductions from natural objects. There are, for instance, snakes and frogs which have been made on the bias and from the life. The snake is etherized under a bell jar, then taken out and greased with sweet oil and replaced in the bell jar, while a sufficiency of thin plaster is mixed with warm water. The snake is then placed on a glass plate and posed. Around him is built an enclosure of four square bars, and the plaster is slowly poured over the snake, the bars confining the cast in a rectangular shape. When the plaster is hard it is freed from the sticks and glass plate and the now defunct reptile is carefully removed, tail first, from his intaglio impression. The plaster cast thus obtained is rendered waterproof by immersion in melted paraffine. A metallic-conducting surface must now be given to the interior of the cast. This is done by moistening the surface of the mold with a solution of silver nitrate and by exposure to sulphuretted hydrogen precipitating the silver on the cast. Conducting wires are now fastened around the edge, and the mold is carefully suspended in the depositing bath. A good firm coating takes about three days to form, and then the mold is softened in boiling water, and carefully broken off.

People have often heard of the incinerating effects of high-frequency currents, but rarely get any prac

tical demonstration. Mr. George P. Low, the well-known electrical engineer of San Francisco, has preserved the remains of two eagles, some storks and other birds, which had short-circuited part of the current of a California transmission line while sitting on the wires, with the result of leaving only their beaks and talons, not a vestige of the bodies or feathers being discovered. Mr. Low is forwarding these curious relics to the electrical exhibition, where they will be mounted in such a position as to show how the thing happened, and just what happened. It will be the first exhibition of the kind that has been made.

It is proposed at the exhibition to have, among other railway apparatus, a working model of track

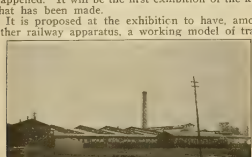


FIG. 2. ELECTROLYTIC WORK AT NIAGARA FALLS.—EXTERIOR VIEW OF MATHIESON ALKALI PLANT.

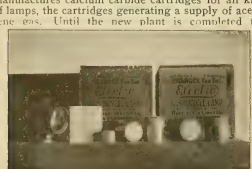
intended to demonstrate the operation of the third-rail system as applied to steam railroads. Colonel N. H. Heft, the electrical engineer of the New York, New Haven and Hartford Railway company, whose work is so widely known in connection with the successful third-rail line between Hartford and New Britain, Conn., has very kindly placed at the disposal of the management blue prints showing the construction of the track, and some of the actual material used. The model track, from 50 to 100 feet long, single and double, and about five inches gauge, is now being constructed on Col. Heft's plans, and will be shown in actual operation during the continuance of the show, the details of the track being imitated as closely as the conditions will allow. Over this track a train of cars will run to and fro continually, showing how the current is picked up and delivered to the motor, and how the switches and signals are included in the operation.

Acetylene for Portable Lamps.

One of the earliest forms in which it was proposed to utilize acetylene was in bicycle lamps and small hand-lamps, as well as those of ornamental design, but owing to the stock-jobbing schemes which the promoters of the industry indulged in the commercial development of acetylene for portable lamps was practically neglected. Now, however, this enterprise is being seriously considered, according to the Niagara Falls correspondent of the Western Electrician, who furnishes the following interesting narrative of the development and plans of the projectors:

"The new factory building of the Buffington Light company is going up rapidly at Niagara Falls. It will be a frame structure 100 by 40 feet at the foundation and two stories high, located on the Niagara Falls Power company's property, adjoining the plant of the Acetylene Light, Heat and Power company on the east. The Buffington company manufactures calcium carbide cartridges for all kind of lamps, the cartridges generating a supply of acetylene gas. Until the new plant is completed the



ACETYLENE FOR PORTABLE LAMPS.

Buffington people are trying to meet the demand for their goods in a small building in the power district. The forms for the cartridges are now made in New York, but when the new plant is in operation they will be made at the Falls. The manager of the Niagara Falls works is H. A. Brognard. The company has a capital stock of $300,000, and is allied to the Electrogas company, which company claims to control the patents on carbide.

"The business of the Buffington Light company marks a new departure in the use of acetylene, or rather in the manner of its application. Men interested in carbide have long predicted great things for it, but its use in lamps for household and other purposes has until recently been more of a fanciful nature than a reality. It is now claimed that the cartridges of the Buffington company make the use of acetylene in lamps clean, simple, practical, without smoke, while giving out a powerful clear white light. In its application the use of carbide is very easy in handling, for to refill a lamp means the simple insertion of a fresh cartridge in place of the one consumed, a process requiring but a moment of time without soiling the hands or clothing.

"At present the company is making three sizes of cartridges. One for bicycle lamps, and Nos. 8 and 12 for table and student lamps. In the accompanying illustration the comparative sizes of these cartridges is portrayed faithfully. First to the left is seen an Electro bicycle lamp, and next to it a box in which 12 bicycle cartridges are packed. Next comes one of the bicycle-lamp cartridges; next two No. 8 cartridges, and then two No. 12 cartridges. The cases in the background hold one gross of bicycle-lamp cartridges, or 12 of the smaller boxes next to the lamp.

"All the cartridges are made in two parts, one sliding over the other to allow for expansion. When the consumed cartridge is removed from the lamp it is always found in its extended form, the residue occupying more space than the original carbide. The cartridge used in bicycle lamps is about 1⅝ inches in diameter by 1¼ inches deep. The carbide with which it is filled is about the size of wheat, and will furnish a supply of gas sufficient to last 3½ to four hours. Both the top and the bottom of the box are perforated, the top being distinguished from the bottom by a large hole in the center. The interior is supplied with an absorbent, the bottom being covered, four divisions being created with a white absorbent, while a blue absorbent is placed at the top, thus furnishing an additional means of distinguishing between the two ends. In charging the lamp the water valve is closed tight, the water chamber is filled with clean water; the charge is placed on the bottom of the lamp with a spring over it, and then the two parts of the lamp are fastened together on very much the same principle as an oil lantern. To start the lamp the water valve is opened by turning a finger-piece to the left, and in a few seconds gas will generate and the flame will light by simply holding a lighted match to the opening of the chimney at the top of the reflector. The proper height for the flame is about half an inch. The light will not jolt out, as is the common cause of regret among wheelmen over their oil lamps, but when it is desired to put it out the valve should be closed some minutes before the time it is desired to extinguish it, so as to shut off the water and stop the generation of gas. The light will go out as soon as the gas remaining in the chamber is consumed. The size of the flame is regulated by the valve-screw which governs the flow of water. If the flame blows it is good evidence that water is flowing on the carbide too freely, and, on the other hand, if the flame grows dim, it may be taken as a sign that more water should be allowed to reach the carbide. The manufacturers state that none of the cartridges will generate a sufficient amount of gas to explode the lamps in which they are used. The place to attach the lamp to the bicycle frame is preferably to the head, just below the handle bars. It should be in a perpendicular position, not inclined forward, as its reflector is designed to throw the light in front of the wheel.

"Cartridges Nos. 8 and 12 are also made of t.n. No. 8 is filled with carbide about the size of corn and No. 12 about the same size or a little larger. Both have a perforated standard in the center. No. 8 will give a supply of gas for four to five hours, while No. 12 will last seven to 7½ hours. No. 8 will use about 12 ounces of water, and No. 12 about 16 ounces in throwing off its gas. The time given as the life of the cartridges while in use is considered in connection with a half-foot burner. The size on an Electro gas lamp indicates the size of cartridge it requires.

"It is evident that the lamps may have many forms, and it is possible that in the future the company will develop some novel styles. The Niagara plant will be equipped with the necessary machinery to make the cartridge boxes and necessary parts. As it is located near the Acetylene Light, Heat and Power plant, it will be in close touch with a supply of carbide. An electric motor of small size will be installed to operate a grinding machine."

Fribourg Accumulator Plant.

The town of Fribourg, Switzerland, which lies on the Sarine River, has a water power remarkable for its constancy, and the people have not been slow to avail themselves of it for supplying the town with water, railway privileges and electric illumination. The normal output of the stream was entirely exhausted when the railway was supplied, and as more power was required recourse was had to the storage battery.

In the present plant there are three turbines moving under a head of 10 meters, the first turbine of 500 horse power actuating two generators of the Thury type of 500 amperes at 350 volts each. Current is delivered at 300 volts to many commercial motors which take over six horse power, and to

FIG. 1. FRIBOURG ACCUMULATOR PLANT.—GENERAL VIEW.

the street-car lines, which consume 60 horse power for each two cars in motion. A second turbine of 300 horse power is direct-connected to two Thury dynamos of 500 amperes at 150 volts each, for feeding the electric lights and operating motors of less than six horse power. These dynamos also supply suburban customers above Fribourg proper. They are also utilized to charge the accumulators which supply the lighting circuits in the remote sections of the town. Finally, several motors of from seven to 30 horse power receive current from these generators while the batteries are being charged during the daytime. The third turbine, also of 300 horse power, actuates the water works pumps, raising the public water to a height of 150 meters above the river.

The accumulator equipment is in the basements of the old Hotel de Ville (Fig. 2). To this point the lines from the dynamos are brought, and from here the six feeders of the urban system issue. These basement rooms are particularly well situated for the purpose. The batteries installed are of the German-Swiss type.

The principal advantages claimed for these batteries, aside from their cheapness, are their light weight and their solidity, resulting from the mode of construction. Each plate, whether positive or negative, is inclosed in a perforated celluloid frame. The active material is thus forcibly held in the lead grid, which is the skeleton of the plate. Again, it is claimed the celluloid serves to strengthen the plate and prevent injury through mechanical forces, while permitting of large latitude in quick charging and discharging.

The installation includes two batteries of 83 elements each, and of 2,600 ampere-hours capacity, at a rate of 130 amperes, or one ampere per kilogramme of plate. This capacity descends to 2,000 ampere-hours for a discharge of 200 amperes, and to 1,400

ampere-hours at a 400-ampere rate. These capacities have been calculated for a fall of tension of 10 per cent.

The normal intensity of the charging current is 200 to 250 amperes and the maximum 350 amperes. While charging the mean potential of each element is 2.3 volts and in discharging it is about 1.96 volts.

Each element is made up of 50 plates, 250 millimeters long by 200 millimeters wide, in glass cells; 24 positive and 26 negative electrodes. The weight of a positive plate is 2.8 kilogrammes, and of a negative 2.5 kilogrammes, so that the entire weight of an element rises to 138 kilogrammes, including the soldering and connections.

The plates are held apart by projections of celluloid attached to the case of the same material which surrounds the plates. The electrodes, both positive and negative, are supported by two plates of glass which stand edgewise on the bottom of the cell and hold the plates by lugs of lead.

Each cell rests in oil insulation, upon wood, this being further separated from earth by oil insulators.

The acid used has a density of 23 degrees Baumé, each cell containing about 50 liters. The two cells constituting one element are connected by a glass syphon, so that the density of the two parts of the element shall remain always the same.

The tension required at the distribution board is constant up to the end of the discharge. The current required can never surpass 175 volts, while all the cells can furnish at least 246 volts.

Fig. 3 shows a combination for charging composed of a motor of 50 horse power at 300 volts, mounted on the same shaft and the same base as two generators of 25 horse power each, producing a continuous constant current of from 30 to 80 volts. The motor is of the Lundell type, of six poles, with but one exciting coil, while the generators have four poles and four exciting coils. The three drum armatures have toothed cores, with the Alioth winding. This combination makes 800 turns per minute. Automatic circuit breakers guard against a possible discharge backward from the accumulators. These, of which there are four, are made up of an electro-magnet of the horseshoe pattern and two coils. One of these coils, provided with a large wire winding, is traversed by the charging current, and eventually by the return current from the battery. The other spool, wound with fine wire, is constantly excited by an independent current, and, according to requirements, connects or disconnects the apparatus.

When the charging current flows through the circuit breaker the magnetic attraction exercised by the magnet is the sum of the attraction set up by the two spools. But if for any cause the battery current backs up through the coil, the spring overcomes the little remaining attraction, when the armature is released, and by proper attachments opens the circuit.

All the accessories are mounted upon four distribution tables (Fig. 1). The first comprises the apparatus pertaining to charging, the second that utilized in the discharge, and the others to the automatic regulators of the batteries. These automatic regulators work on the relay principle, and actuate a commutator automatically.

Several Pittsburg traction companies have combined for the purpose of erecting and maintaining a storage battery plant which will supply current to the trolley systems entering into the agreement. This scheme has many attractive features that should prove applicable wherever large trolley systems are operated.

Electrical Equipment of Plating Plants.

By C. F. Burgess.

Although the electro-deposition of metals existed before the advent of the dynamo, and was in fact one of the first uses to which the dynamo was put, it is noticeable that this branch of electrical industry has not shared the rapid improvement and development of later years that is so marked in other electrical industries.

The extent and importance of the electro-plating industry in this country may be hard to estimate, but figures which were given some time ago gave the number of plating plants of some considerable size as 392, with a total capital of $38,000,000 and an annual output worth $3,400,000. These figures do not include the plants devoted to the galvano-plastic arts and the small equipments which are operated in connection with many manufacturing concerns.

The deposition of metals by means of electricity for ornamental and protective purposes has by no means reached its ultimate development, for, aside from the increasing use of coatings of copper and nickel, the so-called galvanizing of iron by dipping into a molten bath promises to be replaced by electro-deposition of zinc from an aqueous solution, owing to the many advantages which such a process has over the old method.

It may seem strange, then, that this electrical industry is one almost entirely neglected by the electrical engineer. The problems which arise here are largely of a chemical and of an electrical nature, but it is very seldom that a practical plater thoroughly understands the laws of electricity, and even less common to find one who may be called a chemist.

There are a number of reasons for this state of affairs. In the early days of plating the greatest possible secrecy was maintained among those engaged in the work to prevent processes and improvements from becoming generally known. This tendency still exists at the present time, and many of these plants exclude visitors on this ground, although it may be said to be secrecy without any secrets. Such a condition has a tendency to prevent the general knowledge of new processes and ideas which may be used.

There are very few plating equipments which cannot be criticized from the electrical standpoint. The dynamos are usually small shunt-wound machines, without regulating devices, or with unsatisfactory ones. The commutators are smaller than they should be, and, owing to the very large currents carried, the sparking is very destructive. Such a machine will give a high voltage at light loads (when there is little work in the tanks), when a lower voltage is desirable. Owing to the armature reactions and the armature drop, caused by the large current, the voltage drops rapidly when there is a considerable demand for current and when a higher voltage is desirable to compensate for losses in other parts of the circuits. Various regulating devices have been used, such as a rheostat in the field circuit and plugging arrangements for cutting in and out portions of the turns on the field windings. Such machines do not automatically take care of the variations caused by varying current, and require constant hand regulation and attention.

In choosing a dynamo for a plating plant, considerable difficulty may be experienced in determining what size of machine to use, owing to the unsatisfactory methods which manufacturers use in rating the machines. The dynamos are usually rated as capable of supplying current to a given number of gallons of solution. This is a very uncertain way of giving the current capacity of the machines, for the current density in one solution may be greater than should be used in another solution, and, in addition, the current which a plating tank of a given current content will require, when full of work, depends upon the shape of the tank and the relative position of the electrodes. To obviate the former difficulty, it is customary to rate a machine in its capacity to supply current for a given number of gallons of copper solution, another number of gallons of nickel, and still another for silver. The second difficulty still leaves the purchaser in the dark as to what size of dynamo to order. A cyanide of copper solution will allow of a current density being used which is small, three or four amperes per square foot of cathode surface, while in a copper sulphate bath the current density may be increased to 40 amperes per square foot, so that the size of dynamo to be used for a given amount of solution depends not only on the metal to be deposited, but also on the nature of the solution.

A much more satisfactory method would be to use the method of rating which the manufacturers of other classes of electrical machinery adopt, giving the capacity in watts, or, perhaps better, in am-

FIG. 3. FRIBOURG ACCUMULATOR PLANT. -MOTOR AND GENERATORS.

FIG. 2. FRIBOURG ACCUMULATOR PLANT. -BATTERY ROOM.

peres. A plater may then, by his knowledge of the current density which he can use, and the amount of material which he wishes to plate, readily choose the machine which will do his work.

From the considerable demand which exists for a good plating dynamo, a number of the representative manufacturers have lately taken up the question, and are placing on the market very satisfactory machines. They are usually shunt machines, operated at five to six volts pressure. The design of such machines involves some questions which do not arise in the design of those to be used at a higher pressure. The low voltage makes the question of field excitation somewhat difficult. Large commutators, large brush-bearing surfaces and the use of copper brushes are necessary to avoid the heating and destructive sparking caused by the excessively large amounts of current which they are called upon to

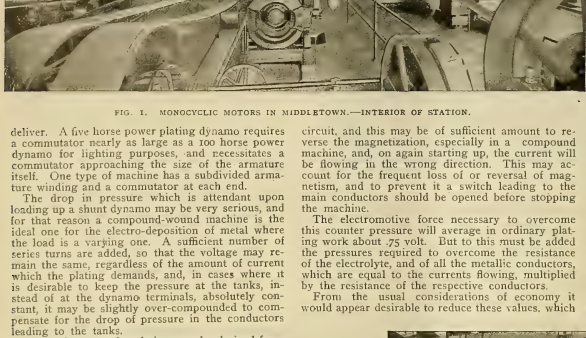


FIG. 1. MONOCYCLIC MOTORS IN MIDDLETOWN.—INTERIOR OF STATION.

deliver. A five horse power plating dynamo requires a commutator nearly as large as a 100 horse power dynamo for lighting purposes, and necessitates a commutator approaching the size of the armature itself. One type of machine has a subdivided armature winding and a commutator at each end.

The drop in pressure which is attendant upon loading up a shunt dynamo may be very serious, and for that reason a compound-wound machine is the ideal one for the electro-deposition of metal where the load is a varying one. A sufficient number of series turns are added, so that the voltage may remain the same, regardless of the amount of current which the plating demands, and, in cases where it is desirable to keep the pressure at the tanks, instead of at the dynamo terminals, absolutely constant, it may be slightly over-compounded to compensate for the drop of pressure in the conductors leading to the tanks.

Where the power for plating may be derived from direct power or lighting circuits, the most desirable arrangement is a motor-dynamo, in which the fields of the dynamo, or low-pressure end, are excited directly from the high-pressure mains. In this case, compounding would not be necessary, for the armature reactions and losses would not have an equal effect in lowering the voltage that would exist in an ordinary shunt machine, and, if desirable, a field rheostat would enable the voltage to be maintained at any desired value.

The consumption of electrical energy delivered by the plating dynamo is expended in overcoming the resistance of the conductors leading to the tanks, the rheostats for regulating the current in the separate tanks, the anode and cathode supports, the resistance of the electrolyte, and finally in the actual energy required for the deposition. The amount of energy required to deposit a metal out of an electrolyte, in which metal goes into solution at the anode as rapidly as it is removed from the solution at the cathode, is theoretically a very small amount, for as the chemical nature of the solution remains the same, there is no change in the chemical energy and consequently no demand for the electrical energy. If an insoluble anode is used, the chemical nature of the electrolyte will change, the solution will become "stripped" of metal, which chemical change necessitates the consumption of electrical energy. If the anode does not supply metal to the solution rapidly enough, which will occur if such surface is too small in comparison with the surface to be plated, not only does the solution become weaker, but a larger consumption of energy or a higher electromotive force is needed.

As a matter of fact, the energy necessary for the deposition from a solution which remains constant is quite an appreciable amount. This is due to the fact that the solution in the neighborhood of the cathode becomes deficient in metal, while in the vicinity of the anode it is more dense, thus setting up an electromotive force and forming what is known as a concentration cell. If the current density is great enough to produce liberation of gases, hydrogen at the cathode and oxygen at the anode, this electromotive force is further augmented. This electromotive force, ordinarily termed the counter electromotive force of polarization, is in opposition to the electromotive force applied at the tank terminals, and consequently a pressure high enough to overcome this polarization must be applied before the current will flow. The amount of this counter pressure may vary between a small fraction of a volt to over one volt, depending upon the current density, character of solution, and whether the solution is agitated. A circulation of the electrolyte will, of course, tend to keep the liquid uniform throughout and tend to remove the gases which are liberated at the metal surfaces. In copper refining this value is about .02 volt, and in ordinary nickel-plating bath it may vary between .5 and one volt. This pressure may be measured fairly accurately by connecting a voltmeter between the electrodes, and then suddenly interrupting the current which is flowing through the tank, and immediately taking the voltmeter reading.

This counter pressure will, of course, send a current in the wrong direction through a dynamo when it is stopped without opening the external circuit, and this may be of sufficient amount to reverse the magnetization, especially in a compound machine, and, on again starting up, the current will be flowing in the wrong direction. This may account for the frequent loss of or reversal of magnetism, and to prevent it a switch leading to the main conductors should be opened before stopping the machine.

The electromotive force necessary to overcome this counter pressure will average in ordinary plating work about .75 volt. But to this must be added the pressures required to overcome the resistance of the electrolyte, and of all the metallic conductors, which are equal to the currents flowing, multiplied by the resistance of the respective conductors.

From the usual considerations of economy it would appear desirable to reduce these values, which can be done only by reducing the resistance of the various conductors. The resistance of the solution may be diminished by using concentrated solutions or by the addition of common salt or some similar chemical compound, which will aid in the conductivity but which will not take part in the chemical reactions. The resistance of metallic conductors would be made small by the well-known method of using copper of generous cross-section. The ordinary voltage of the plating dynamo may be taken as five volts, which, as compared with .75 volt, would give an energy efficiency of 15 per cent., or, allowing two volts between electrodes, as that which is necessary to overcome electrolyte resistance and counter electromotive force, 60 per cent. of the energy is seen to be lost in the conductors and rheostats. The method for saving this energy would be to reduce the voltage of the dynamo and use large copper conductors. A question of electrical design enters here, and makes it difficult to get a dynamo to operate satisfactorily and efficiently on a very low voltage; also, when a number of different plating solutions are used, different voltages are necessary and the dynamo must operate at the highest pressure required. This, then, makes the efficient consumption of electrical energy in a plating room out of the question.

The cost of power consumed, even under present inefficient methods, in a plating plant, not including that for grinding and polishing, is a very small percentage of the value of the product, and considerable economy of power may be sacrificed in order to turn out work rapidly. Where different solutions are operated, requiring different voltages, it is self-evident that power which is equal to the current of each tank multiplied by the difference between the voltage which it requires and that of the dynamo must be absorbed in the conductors and rheostat leading to the tank. A saving of power would be effected by placing two or more of the tanks in series, instead of the usual multiple arrangement, but to do so would require an equivalent amount of work in each tank, so that this complication would far outweigh the advantages derived.

Next to the dynamo, the most important piece of electrical apparatus to the plater is a rheostat in series with each tank. It is well known that the character of deposit depends upon the current density at the cathode. We may suppose, for example, that the average pressure between the main conductors is about 3.5 volts. This might cause a sufficient current to flow through a cyanide copper solution to give a good deposit, while in the nickel solution it might cause the work to become "burned," to avoid which a rheostat in series with the nickel bath is necessary to reduce the current flowing to a value consistent with a good deposit. Again, a pressure of 3.5 volts might cause a good deposit when the tank is full of work, but if the amount of cathode surface is less, as when removing the plated articles, this same voltage may cause the formation of a dark deposit. This is due to the fact that the current does not vary as the area of cathode surface varies (assuming the anode surface to be kept the same), for the resistance of the electrolyte does not depend upon the cathode surface alone. This is contrary to information frequently given in instruction books for platers, in which statements are made that if the voltage is kept constantly at a fixed value there is no danger of irregularity of deposit. For this reason, also, a rheostat is desirable to regulate the current to suit the amount of work in the vat.

Two primitive methods are not infrequently in use to regulate the current. One is to hang anode plates on the cathode bar to protect neighboring work from burning. Another is to connect anode and cathode bars through a rheostat, shunting part of the current and producing a sufficient drop in the conductors leading from the dynamo to reduce the voltage at the tank terminals. The wastefulness of either of these methods is self-evident.

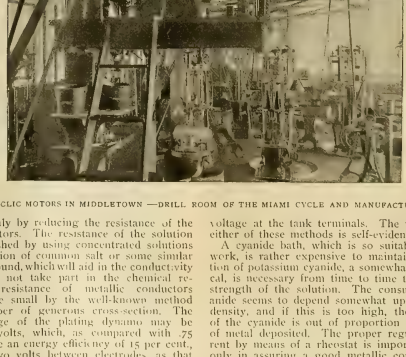

FIG. 2. MONOCYCLIC MOTORS IN MIDDLETOWN —DRILL ROOM OF THE MIAMI CYCLE AND MANUFACTURING COMPANY.

A cyanide bath, which is so suitable for general work, is rather expensive to maintain, as an addition of potassium cyanide, a somewhat costly chemical, is necessary from time to time to keep up the strength of the solution. The consumption of cyanide seems to depend somewhat upon the current density, and if this is too high, the consumption of the cyanide is out of proportion to the amount of metal deposited. The proper regulation of current by means of a rheostat is important, then, not only in assuring a good metallic coating, but also in preserving the solution.

A suitable rheostat requires considerable attention to its design and construction. One designed for use with a copper-sulphate solution may not be suitable for an equal amount of cyanide solution, and for this reason should be designed for the work in hand. It should be capable of carrying the total current of the vat without excessive heating, should be so subdivided as to allow close regulation and

constructed so that the contact points shall have plenty of bearing surface.

The most efficient working of a plating plant means a maximum output of plated work for a given equipment, and for this reason, as well as to get uniformity of work, it is desirable to always use as high a current density as is consistent with good work. Most expert practical platers regulate the current density by the appearance of the work, and such instruments as an amperemeter and voltmeter are regarded as a luxury instead of a necessity, but there is little question that a liberal and intelligent use of such instruments would do much to correct the mistakes which are so common, and that, used in connection with suitable current-regulating devices, it would result in actual saving by increasing the production, rendering the plating more uniform, and in the economy of solution and of power.

Some measurements recently made with an ammeter and voltmeter in a plating plant of the ordinary type are instructive. The tanks were four in number, three for nickel and one for copper, the capacities being 500 gallons, 200 gallons, 75 gallons and 150 gallons respectively. The dynamo was a well-built machine, shunt-wound, of 2,000 watts capacity (400 amperes at five volts), and the conductors to which the tanks were connected consisted of heavy copper wire, No. 0, B. & S. The rheostats were crude affairs of heavy iron-wire spirals, connections being made by the insertion of a copper wedge between adjacent rheostats. The results were as follows:

Speed of dynamo	910 r. p. m.
Average current delivered by dynamo	120 amperes
Average pressure at dynamo terminals	5.2 volts
Average pressure between anode and cathode	1.9 volts
Average drop in copper conductors	.1 volt
Average pressure electromotive force of polarization	.75 volt

This gives a consumption of power distributed as follows:

In overcoming counter-electromotive force	120 × .75 = 90 watts
Power actually consumed in tanks	120 × 1.9 = 228 watts
Power absorbed in rheostats	120 × 5.2 − 1.9 = 384 watts
Power absorbed in conductors	120 × .1 = 12 watts
Power delivered by dynamo	120 × 5.2 = 624 watts
Percentage of power consumed in tanks	36.5 %
Percentage of power consumed in rheostats	61.5 %
Percentage of power consumed in conductors	1.9 %

Assuming an efficiency of 75 per cent. for the dynamo, the consumption of power in the plating plant = 624 ÷ .75 = 832 watts = 1.1 horse power.

A number of measurements made by connecting the voltmeter terminals to the separate anode plates and the tank rods to which they were connected, or rather supposed to be connected, showed an appreciable electromotive force in a number of cases, indicating that the contact between plates and rods was no better than a number of the anode plates were not doing their full share in furnishing metal to the solution, which might be of sufficient amount to "strip" the solution of metal, and thus necessitate the continual addition of metal salts. A voltmeter is therefore a good instrument for the detection of poor contacts and defective connections, which might otherwise be difficult to locate.

A marked saving of power could be effected by reducing the voltage of the source of supply, thus reducing the amount of power which is otherwise necessarily absorbed by the rheostats, though, as previously mentioned, this might make the satisfactory working of the dynamo more difficult.

As less than two per cent. of the power is lost in conductors, there could be no further improvement here, and in fact there is more copper installed than could be profitably saved by the conductor-has to be absorbed by the rheostats. It may then be said that there is some justification for the quite extensive use in plating plants of brass tubing instead of solid copper, and that there is not so much need of applying the ordinary precautions for economy in electrical conductors that are used in electric-light and power-transmission lines. The requirements for conductors are that they shall carry the current without dangerous heating, and without a sufficient drop to reduce the voltage to a value lower than that needed by the tanks.

The above conclusions would apply only to electrodeposition plants where solutions of different character are used, and where the amount of work in the tank varies, and could not be followed in the case of deposition for refining of metals or in extensive electroplying plants.

Monocyclic Motors in Middletown.

During the last two years the number of central stations using that modification of the single-phase alternating system known as the monocyclic, by which current may be supplied to both lamps and motors at the same time from alternating-current generators, has greatly increased. With this system it was found that both arc and incandescent lamps, as well as induction motors, could be supplied from the same alternator, the first-named operating directly from the ordinary two-wire single-phase circuits, the motors merely requiring a third wire to give a displaced voltage.

An interesting example of the introduction of the monocyclic system into a direct-current station, allowing the area of its operation to take a wide extension, exists at Middletown, Ohio, where Mr. E. H. McKnight, the president and general manager of the Middletown Electric Light and Power company, has recently found it necessary to increase the monocyclic capacity of his plant to meet the increased call upon his station. In addition to the arc and incandescent lighting usual in towns of the size of Middletown, certain factories under progressive managers have adopted electrically transmitted power in place of steam, and the motor load on the station already far exceeds the lighting load.

The station fronts on the Miami and Erie Canal, having the tracks of the M. and C. railroad immediately behind it. It is 65 feet wide and 115 feet long. Steam is supplied from two Brownell & Co. Dayton boilers to one 450 horse power compound condensing Buckeye engine and one 300 horse power four-valve Russell condensing engine. The generating plant (Fig. 1) consists of two General Electric 12-pole, 150-kilowatt, 1,040-volt, 600-revolution monocyclic generators excited by two 1½-kilowatt exciters, three 50-light Thomson-Houston series arc dynamos and one General Electric 100 horse power 500-volt direct-current generator, all driven from countershafting furnished with the necessary friction clutches. The 500-volt machine is used exclusively to furnish direct current to several small motor

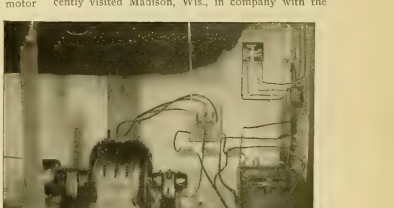

Fig. 5. Motor No. 2 in Factory of the P. J. Sorg Company.

MONOCYCLIC MOTORS IN MIDDLETOWN

plants throughout the city; the arc machines operate 112 city arc lamps.

The motor load on the monocyclic machines runs up to nearly the limit of their capacity. The factory of the Miami Cycle and Manufacturing company, a little over a mile away from the station, takes 200 horse power when its motors are running at their rated capacity, and considerably in excess of this under usual working conditions. The current is received in the factory in six 40 horse power, one 20 horse power and two 10 horse power transformers, reducing the pressure to 115 volts. The motor circuits run from the 40 horse power transformers, the lighting circuits from the three 10 smaller capacity, and all the current is measured in a recording wattmeter connected on the primary circuit. The motor equipment consists in all of 10 General Electric induction motors, three of 20 horse power in the machine shop driving 88 machines, one of 10 horse power in the drill and pattern room (Fig. 2) driving 20 machines, another of 10 horse power driving the machinery in the frame department, three of 30 horse power in the polishing room (two for the polishers and one for the 48-inch exhaust fan), one 40 horse power driving two plating dynamos in the plating room, and another of similar capacity operating a number of small machines in the assembling room (Fig. 3), as well as a three-phase 20 horse power induction motor in the factory number 750, of which during the rush season almost all are lighted.

In addition to the cycle factory Mr. McKnight furnishes power to the tobacco factory of the P. J. Sorg company, for which two departments are already equipped, each with a General Electric 30 horse power induction motor. The first (Fig. 4) is the smoking-tobacco department, on the first floor, and is belted to shafting operating on the three floors above, three Caldwell pickers, one cutter, two granulators and two dust machines. The second motor is on the sixth floor (Fig. 5), and is shown with the transformer and the motor to which the primaries from the station are connected. From this point secondaries are carried to motor No. 1 in the smoking-tobacco department, distant about 500 feet, and the lights in the different departments being tapped off before the motor is reached. Motor No. 2 drives two 7½-inch Sturtevant fans used to dry all the tobacco. It also operates a five-ton elevator. The capacity of the drying department is 100,000 pounds of tobacco daily.

The benefits of electric drive by induction motors are, perhaps, nowhere more forcibly demonstrated than in these two installations. In the cycle factory the constant speed of the machinery, the absence of vibration and the power of the motors to respond to calls reaching as high as 50 per cent. over their rated capacity, have enabled the manufacturers to give to every part of their wheels a perfect finish, as well as to greatly increase the output. In the tobacco factory, the steady rate at which the tobacco passes through the dryers gives it a uniform cure. Previously, the speed being variable, the tobacco would dry in spots only, and a second handling was almost always necessary. According to the foreman, the motor "saves him lots of time."

The incandescent lights in the town already wired number 3,800. Of these 750 are in the cycle factory, 100 are in the tobacco factory, 650 are in the opera house and 2,300 in other parts of the town. These lamps burn with no interference from change in the motor load; in fact, the entire motor load may be thrown on or off without in the least affecting the burning of the lamps, the presence of the motor load being usually only determined by reference to the ammeter. The monocyclic machines operate with almost perfect regulation, requiring little or no attention to maintain the constant potential at all times.

Reorganization of the Madison Electric Railway.

S. M. Hamill of the Brush Electric company recently visited Madison, Wis., in company with the committee of bondholders of the electric railway of that city to arrange for the reorganization of the property. The committee purchased the property from the receiver and reorganized it under the name of the Madison Electric Railway company, and elected Major F. W. Oakley, who is clerk of the United States District Court of Madison, president, George W. Russell of Cleveland, Ohio, vice president, H. R. Newcomb of Cleveland, treasurer, and George Shaw of Madison, manager. The executive committee of the board of directors consists of Messrs. Newcomb, Russell and Hamill. Since the bondholders' committee has been giving attention to the property the whole system has been reorganized and newly equipped with a complete summer equipment of open cars and "G E 800" motors. A new five-years' contract was entered into with the local electric-light company for current and about $7,000 set aside for additional improvements, in addition to a new brick car-barn, which will be built some time this year. Madison is considered by many the best street railway town of its size in the country. This is partially due to the fact that it lies between two lakes and is long and narrow. The citizens of the town built an extension costing about $12,000 and presented it to the road under an agreement that the company was to operate it.

The present owners of the road contemplate many changes that will assure first-class service, and the people of Madison are well pleased with the arrangement.

Joseph P. Smith, Bertram S. Morrill, John W. Kaiser, Bernard T. Warthen and Theodore E. Dollard have incorporated the Heat, Light and Power company of Baltimore, with a capital stock of $10,000. The company is authorized to conduct and operate overhead wires for illuminating purposes and to furnish motive power for machinery and such other purposes as electricity may be used. It may also lay underground pipes or conduits to contain wires.

Western Electrician.

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO.

TELEPHONE, MAIN 1746.

EASTERN OFFICE: 108 TIMES BUILDING, NEW YORK.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, news, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN — **the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own.* This is a CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

HIGH WATER MARK

CIRCULATION, 20,000.

State of Illinois, County of Cook—ss

Frank Forster Kenworthy being duly sworn deposes and says that he is a resident of the city of Chicago, in the county of Cook and state of Illinois, and that he is the superintendent of the Binding department of the Electrician Publishing company, the publishers of the Western Electrician; that he was present at and superintended the binding of No. 24 of Vol. 20 of the Western Electrician, issued on June 12, 1897, and that there were sent out by actual count 20,000 complete copies of said Western Electrician of the volume and number above specified.

And further this affiant sayeth not.

FRANK FOSTER KENWORTHY.

Subscribed and sworn to before me this 27th day of July, 1897. Chicago, July 27, 1897. IRA B. JONES, Notary Public.

Four Years' Record of Electric Light Convention Advertising.

Issue	Number of Advertising Pages.	Whole Number of Pages.	Square Inches of Paid Advertising Matter.

Time is money in the Yukon Valley, and in Dawson City the gold seekers are bound to make the most of every minute. At least they are not going to waste any more time in conveying messages from one point to another. A telephone-exchange equipment is now on the road to that point and will soon be in operation. A 100-number switchboard and 100 instruments comprised the first installment.

An interesting incident in the Cuban complication was the announcement of the sale of the street railways last week. A dispatch from Havana on March 25th said: "The control of all street-railway lines has been transferred to an English syndicate. The Spanish owners apprehend confiscation by Americans or insurgents." Another explanation is that the fear of forced loans had something to do with it, as Sagasta notified the autonomistic government that after May Cuba would be expected to raise money for its own maintenance. At any rate the newspapers have modified their abuse of Americans temporarily and are now reproaching the Spanish who have parted with their railway securities. They interpret this action as a reflection on the power of the Spanish government, claiming that the sales indicate that while the foreigners have confidence in the future of the island the Spanish have no belief in the permanency of their control over it.

Along with the other preparations that the government is making to meet the crisis now pending in the Cuban controversy, is the completion of a system of telephonic and telegraphic communication between the several coast defenses and Washington. Telephone equipments have been ordered for several points along the seacoast, and special telegraph lines are being strung between important points to insure communication. From Washington comes the news that among the emergency preparations that have been made is a large increase in the telegraphic facilities of the white-house and the Navy and War departments.

Long-distance telephones have been supplied and the telegraph companies have strung seven additional wires to the War and Navy departments, and several additional connections have been made with the executive mansion. Cable communication with Cuba is being watched closely at this time and unusual precautions have been taken to ensure the satisfactory working of the line.

Col. Frank, commandant at Fort Henry, has made a remarkable statement concerning the condition of that point. Wires have been laid from Capes Charles and Henry across the channel leading into Chesapeake Bay and Hampton Roads, and submarine mines or torpedoes could be attached to them with very little trouble or delay. This work will no doubt be carried to completion as quickly as possible, because Fort Monroe would be utterly ineffective against the Spanish torpedo flotilla should it make an effort to pass that fortification, according to the commandant.

Conflicting statements concerning the policy of the city administration toward the Chicago street-railway corporations upon the subject of fenders have been issued by the law department and commissioner of public works. The street-railway corporations have contended that the ordinance under which Mayor Harrison proposed to act was invalid and they have acted accordingly. Now Corporation Counsel Thornton takes the same position. When the subject was brought to his consideration on Monday last he held that the fender ordinance was invalid, and, on the request of the mayor, drew up a new ordinance, which is exactly the same as the first one, except that it provides for basket fenders instead of any type that may be approved by the mayor and the commissioner of public works.

Another announcement was made on Wednesday, when it was said that Mayor Harrison had determined to make an attempt to enforce the present fender ordinance in spite of the fact that Corporation Counsel Thornton had decided that it was faulty in form. The mayor and Commissioner McGann had a long conference over the matter on Tuesday. They concluded that it would be difficult to get the council to pass another ordinance, as the street-railway companies would be sure to fight it. The present measure was introduced at a time the companies were not looking for it, and went through before opposition could be organized. The mayor has, therefore, determined to make a test of the present ordinance before abandoning it entirely.

The commissioner of public works is reported as expressing the opinion that "there is something more than the fender ordinance at stake in this matter. The principle of how far I can superintend the construction of work done under city ordinances is to be determined. If I can say what kind of fenders are suitable, then the Nelson ordinance is a good one, and that is the point we have got to have passed upon. I shall have prosecutions against the companies begun at once."

It may be mentioned that the street-railway companies have welcomed the issue, as they are anxious to have their position determined by the courts. The legal departments of all the street-railway companies of Chicago are unanimous in pronouncing Mr. Thornton's position correct in this matter. The outcome of the controversy will be watched with interest by street-railway companies throughout the country.

Marine testing tanks are now generally employed for the determination of many important facts bearing upon the design and construction of naval vessels, and invaluable data have been obtained by this means, but this information is in the possession of the governments that have discovered it, and it is zealously guarded in their naval archives. Marine engineers find it difficult and sometimes impossible to secure statistics of great value, because of the lack of facilities for individual research and experiment. For this reason the announcement that a marine testing tank for models is being built at Cornell University is commanding attention in engineering circles. It is the desire of Cornell to make experiments which will be in the line of pure science. The idea is to establish a set of general rules or laws which can be used by constructors, to point out exactly what every kind of propeller will do, what every shape of boat will do under varying conditions, how much power would be needed to propel certain boats at certain speeds, and the limitations which would govern these performances. Marine engineering should have a scientific basis, and very little work has been done in this line outside of governmental circles, at least in this country. Government tanks and nearly all private tanks are for the most part occupied with commercial problems, having something to do with a particular ship or a particular propeller, for example, but the information thus gained is locked up. It is for the benefit of government design, and not for the advancement of general engineering science. The Cornell tank will be somewhat similar to that now being built for the government, which has already been described in this journal. The tank in Ithaca has a trolley-car structure extending across it which is capable of being propelled electrically from one end of the tank to the other at any speed. This is for the purpose of testing the speed, thrust and area of propellers. It is also used in connection with the determination of the shape of vessels' hulls. It is supplied with delicate testing instruments. The operator rides upon it as it moves along the tank, dragging after it the model of a man-of-war in the water, or a special apparatus carrying small propellers. The operator can work the structure by means of switches in circuit with the electric motors. If the model of a boat is being tested it is placed in the water under the trolley structure and drawn forward by a vertical metal rod, which extends up through the structure and impinges upon a recording mechanism. The completion of this tank will give this country two valuable equipments, the most perfect in the world, as the government tank now being built is fully equipped with the latest instruments, and is said to be the largest in the world. Great Britain has two marine testing tanks, one at Portsmouth, which is owned by the government, and another in Scotland, which is not public property. Italy and Russia have each one tank. None of the other great powers have modern testing equipments of this kind.

Death of Nelson W. Perry.

(Special dispatch to the Western Electrician.)

New York, March 29.—Nelson W. Perry, the well-known electrical journalist, author and engineer, died at his residence, 18 Sidney place, Brooklyn, at seven o'clock on Sunday evening. Mr. Perry's death was due to his ardor in pursuing a scientific experiment at his home on Saturday evening. He was at work on an incandescent gas-burner which he had invented, and to observe the success of his efforts it was necessary at times that the room should be darkened. At such a period of darkness Mr. Perry reached for a glass of water and by mistake took a glass containing bichromate of potassium, drinking its contents. The fatal error was immediately discovered, and two physicians were summoned. Emetics were administered, and it was thought that Mr. Perry's life would be saved, as he seemed to rally from the effects of the poisonous draught and to improve during the night. His condition on Sunday morning was much worse, but he gradually rallied and at noon was thought to be out of danger. In the meantime, Mrs. Perry was summoned from Baltimore, where she had been taking medical treatment. She arrived at her husband's bedside at one o'clock. The meeting was an affectionate one and seemed to greatly excite Mr. Perry in his weakened state. He experienced a relapse from which he never recovered, gradually sinking until his death at 7 p. m. W. F. O.

Mr. Perry possessed a rare combination of talents. He had real engineering ability, grace and felicity as a writer and an engaging personality. He was firm, even aggressive, in advancing his own views on engineering and other topics, but he was always courteous, and although widely known, he had few if any enemies. He was well educated and had supplemented his early training by acute observation, original research and wide reading. Yet he was in no way pretentious; he had an inquiring mind and delighted to inform himself on all subjects. He was quick-witted and could be a delightful companion. Not a perfect man by any means, Nelson Perry was nevertheless a very likable one, and his death has brought a pang of genuine sorrow to many hearts.

Mr. Perry's career was a varied one. It shows the versatility of the man. Nelson W. Perry was born in Columbus, O., May 22, 1853. He came of good family. His ancestors were of Puritan stock and his father was an honored judge and a member of Congress. He was educated in the public schools of Cincinnati, and later at Phillips Exeter Academy, Harvard University and the School of Mines of Columbia University. He graduated from the last-named institution with the degree of E. M. at college Mr. Perry was prominent in athletics as well as in his studies. Immediately after graduation he was appointed economic geologist and mineralogist on the United States Geological and Geographical Survey of the Territories. In 1880 he was appointed to the chair of metallurgy at the University of Colorado, and for a number of years thereafter he practiced his profession of mining engineering, both in the Rocky Mountain region and in the republic of Mexico. During this period he did valuable research work in chemistry, evolved a new method for making platinum assays, discovered, analyzed and described two new minerals, which he named gunnisonite and ramasite, from the localities, Gunnison County, Colorado, and Ramos, state of San Luis Potosi, Mexico, near which they were discovered, and contributed several important papers to various scientific societies. At this time he was elected corresponding secretary of the American Institute of Science and Arts, Mechanics' Institute, member of the American Institute of Mining Engineers, foreign member of the Deutsche Gesellschaft fuer Chemie of Berlin and of the Societié Chemique of Paris.

Mr. Perry took up electricity in 1887, and in the following year he gave up mining engineering to go into electrical engineering. For several years thereafter he was connected with a number of the great companies engaged in the Edison-Houston, Brush, Short and Edison General Electric companies. In 1891 he came to Chicago as one of the editors of Electricity, then newly established in this city, succeeding a few months later to the position of managing editor. Not long after that he resigned from the paper and practiced his engineering profession independently, but in a short time he was offered the position of associate editor of Electrical World, in New York, which he accepted. Mr. Perry remained with the Electrical World but a short time, but during the period he contributed a fine series of articles from the World's Fair in Chicago. Afterward he returned, as editor, to Electricity, then, as now, published in New York. At one time Mr. Perry was the associate editor of the Engineering Magazine, and he has written much for the electrical and engineering journals of this country and Atlantic, including the Western Electrician. He was awarded the John Scott Legacy Premium and Medal in 1884 by the Franklin Institute of Philadelphia for his series method of electric traction. He was vice-president of the New York Electrical Society in 1897, and was also a member of the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. Mr. Perry was the author of "Electric Railway Motors: Their Construction, Operation and Maintenance," a useful book for motormen, written in 1894; and his papers on scientific and technical subjects would fill several volumes. Mr. Perry resigned from Electricity a few months ago to accept a position with the New York engineering staff of Westinghouse, Church, Kerr & Co., but this place he had also relinquished a short time before his death.

American Institute of Electrical Engineers.

At the meeting of the Institute in New York on March 23d, a paper by Prof. R. A. Fessenden on "Insulation and Conduction" was presented by R. W. Ryan, in the absence of the author, and discussed by Prof. Frank Iin and Dr. Pupin. About 75 members and guests were present.

The secretary announced that at the meeting of council in the afternoon the following nominees had been selected from the proposals submitted by members:

For president, Arthur E. Kennelly.

For vice-presidents, Robert B. Owens, William Stanley, Cary T. Hutchinson.

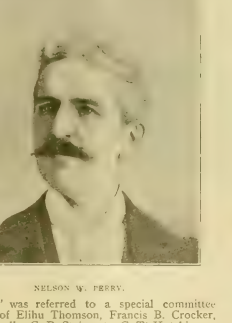
For managers, Herbert Lloyd, Samuel Sheldon, George F. Sever, Charles P. Steinmetz.

For treasurer, George A. Hamilton.

For secretary, Ralph W. Pope.

The following-named officers continue their terms as provided in the constitution: Vice-presidents, A. E. Kennelly, Charles S. Bradley, D. C. Jackson; managers, J. W. Lieb, Jr., F. A. Pickernell, W. L. Puffer, L. B. Stillwell, Alexander Macfarlane, W. F. C. Hasson, Gano S. Dunn, Herbert Laws Webb.

The question of "Standardization of Electrical



NELSON W. PERRY.

Machinery" was referred to a special committee composed of Elihu Thomson, Francis B. Crocker, A. E. Kennelly, C. P. Steinmetz, C. T. Hutchinson, J. W. Lieb, Jr., L. B. Stillwell.

The following-named associate members were elected: Albert G. Davis, Schenectady, N. Y.; Albert R. Gallatin, New York; Herbert Gaytes, Oakland, Cal.; Russell Agnew Griffin, New York; Francis Valentine T. Lee, San Francisco, Cal.; Max Loewenthal, New York; Henry W. Pope, New York; Fritz Reichmann, Austin, Texas; Theodore E. Theberath, San Francisco, Cal.; Robert Anton Fliess, New York.

The opening date of the general meeting at Omaha was fixed for June 27th, and its continuation for either three or four days has been left with the committee on papers and meetings for decision.

Death from Electrical Shock at Low Potentials.

In Germany there has been much discussion of the alleged fact that persons coming with fatal pressure did not exceed 115 volts in any of these cases, but in doing so it did not publish the name of the factory or the precise nature of the processes carried on there. The German dailies appear to have made much out of this article, not omitting to point to the fact that in the majority of installations a pressure of 115 volts is used. The Hanover Union social society at a recent meeting, discussed the harm such articles would do to the electrical industry, and resolved to protest to the Verband Deutscher Elektrotechniker that its organ the Elektrotechnische Zeitschrift should have published the article referred to, and called on it to take steps to obliterate the harmful effect caused by its publication. At the same time the Hanover society has addressed other electrical societies in order to obtain their opinions on the matter.

The Frankfort Electrical society, in considering the circular of their friends in Hanover, has agreed to differ from them entirely, holding that the Zeitschrift is to be commended for calling attention to a hitherto-neglected source of danger. On this state of affairs the London Electrician makes these sensible observations: "While agreeing with the Frankforters that accounts of such accidents should always be published in the technical press, even if only as a warning, we think that too much care cannot be bestowed on the manner in which they are worded. We call to mind several cases nearer home where technical journals have published misleading particulars of this character, which inquiry would promptly have modified. Instead of withholding the name of the works at which the accident occurred, full particulars of all the facts and conditions which could in any way help to elucidate its cause should have been given, and more emphasis should have been put on the fact that this was essentially a 'particular case' from which no general conclusion as to the danger from low-pressure shocks could be drawn. The tendency of the lay press of all countries to make a sensation of any news item that partakes of the mysterious is well known and should be reckoned with in such cases."

Sussman Mining Lamp.

In a paper read before the alumni of the Mining School at Liege, Belgium, G. Nicolas gives an interesting description of the Sussman electric lamp for miners. This lamp is based on the use of a dry accumulator which was adopted in order to meet the objections raised against batteries with liquid electrolyte. The Sussman accumulator uses a paste of paper or cellulose formed into a plastic mass, which gives, it is said, but little more resistance than a liquid electrolyte. Its adhesive quality also serves to protect the electrodes and hold them in place, preventing them from slipping and causing short-circuits. The material used is filter paper reduced to a dry powder. This is moistened with sulphuric acid, but the quantity of acid used is so small that it does not interfere with the portability of the lamp, which can be carried in any position or turned upside down without injury. The active matter used in making the plates is lead oxide in fine powder formed into a paste with a weak solution of indiarubber and sulphate of ammonia.

The lamp is of the usual form in miners' lamps and consists of the case carrying the battery and of an incandescent electric lamp, suitably protected. The battery is composed of lead plates pierced with holes and covered with a paste of lead oxide prepared as described above. The approximate dimensions of the plates are 100 by 56 millimeters and five thick (3.94 by 2.20 inches and 0.20 inch thick); their weight is 230 grammes (0.51 pound) for the positive and 175 grammes (0.38 pound) for the negative.

The ebonite case in which the accumulators are placed is divided into two compartments, inclosing the two elements. It is 125 by 65 by 65 millimeters (4.93 by 2.56 by 2.56 inches) and is placed inside a sheet-iron casing, the outside dimensions of which are 145 by 70 by 70 millimeters (5.71 by 2.76 by 2.76 inches). Each compartment of the ebonite case contains a positive plate and two negative plates separated by two liners of rubber. The whole is covered with a layer of insulating matter, and is provided with a small tube which serves to permit the gases generated to escape, and also to permit the introduction of the acid needed to moisten the electrolyte.

The light is protected by a thick glass cylinder, which is placed above the sheet-iron case, and which has a sheet-iron cap resting on the top of the lamp. The accumulator case and the cap are held together by four small bolts. The joints between the glass and the metal are made tight by rubber rings, which also serve to take up shocks. The cap is provided with a hook for suspending the lamp, and reflector can be placed behind the light. The top is about 70 millimeters (2.76 inches) high, making the lamp in all 215 millimeters (8.47 inches) in height. Its total weight, ready for use, is 1.98 kilogrammes (4.37 pounds). The lighting power is about five times greater than that of the ordinary miner's lamp. The expense of recharging the lamp is not heavy. The power required to charge 1,000 lamps at a time is 3.7 horse power.

A lamp will burn without any attention from 12 to 16 hours. At the Strepy-Bracquegnies colliery in Belgium the cost of the lamp, including all repairs and the renewals of the incandescent film, was found to be 35 centimes (7 cents) per day of 12 hours. The miners preferred the Sussman lamp because it gave a much greater light and it was not necessary to have it so close to the work, nor to change its position often because it was reliable, and because it would give light equally well in any position. At this colliery a lamp was given to each foreman, to each road-cutter and to each group of six coal cutters.

The chief objection which has been raised to it is that it will not serve as a detector of the presence of fire damp, as the ordinary miner's lamp does. It is probably that where this lamp is used some kind of fire damp indicator would have to be provided.

The city of Hagerstown, Md., contemplates the issuance of $60,000 in bonds for the erection of an electric plant to supply light, heat and power.

DEVELOPMENT OF THE TELEPHONE FIELD.

Independent Telephone Movement.

[From the London Electrician.]

To all interested in telephony, but especially such as are interested in the independent telephone movement in the United States—a movement which has been growing since the field has been opened by the expiration of the fundamental Bell patent—the issue of the Western Electrician of Chicago for February 26th may be commended for notice. This number is almost entirely devoted to a discussion and descriptions of the various independent telephone concerns as opposed to the Bell company. It is stated that there are, in round numbers, about 2,500 independent exchanges in operation in the United States to-day.

[From the London Electrical Engineer.]

The great demand now growing in this country for cheaper rates for telephones, and for exchanges to be established on the co-operative principle, gives interest to the speculation as to whether the competition so obtained will be an ultimate boon. With more subscribers, due to cheaper rates and equal trunk-wire facilities, it would appear that much good would result, but it is hardly likely that the National Telephone company would allow their lines to be used for distributing trunk messages. In that case mutual co-operation between the independent exchanges would be necessary to make this opposition at all powerful. It is interesting in this respect to see what has been done in the States. From the technical press it is difficult to gauge the true state of affairs. Certain journals, starting as advocates of the independent exchanges, have veered round, and now damn them as being merely company-promoting schemes. Still, the Bell company is rich, and may have called the tune in these instances. At any rate, we are glad to see the Western Electrician take up the independent exchanges. In the leader of the current number the editor states that * * * [Editorial reproduced from issue of Februray 26th.] We only trust that the opposition movement will not degenerate into an amalgamation in favor of the shareholders, as has been the case in cable work.

Telephones for Coast Defenses.

Both the War and Navy departments have recently placed rush orders for telephone equipments with the American Electric Telephone company of Chicago for the coast-defense forts and for the navy yards. All orders have been marked "emergency purchases" in red ink, indicating that they were to be paid for out of the fund placed at the disposal of President McKinley by Congress. The company shipped on March 28th a full equipment for Pensacola, Fla., and under telegraphic orders is pushing work on other orders for the government as fast possible. The points for which the telephone equipments are destined embrace all coast-defense forts.

P. C. Burns, the president of the American Electric Telephone company, said that the tenor of the orders and the urgency of the telegrams asking for as immediate shipment of the orders as possible were an indication of much more than ordinary need for quick work in the installation of the telephones. The system which the government has chosen for this work is especially adapted for long-distance telephoning. The orders so far are confined to the coast defense forts of the East and South. From both the War and Navy departments, it is said, come many messages asking quick work in preparing and shipping these supplies, and each day for the last two weeks has brought new orders for additional equipments.

A Bell Investment.

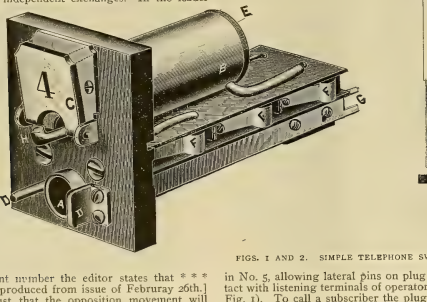
The Electric City Telephone company of Great Falls, Mont., an independent company, has sold its exchange to the Rocky Mountain Bell Telephone company, and the announcement was made by Manager Wade that the service would cease March 31st. A circular has been sent out explaining that it proved more expensive to conduct the exchange than had been anticipated. One of the stockholders has secured a temporary injunction to stop the sale, and he claims it is the result of a conspiracy.

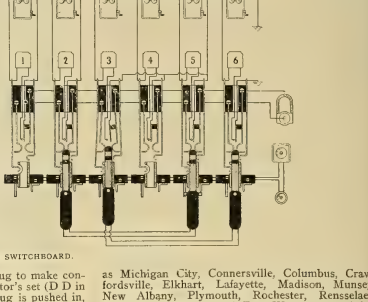
Simple Telephone Switchboard.

After several months of experimental work the Graham Electric company, Rialto building, Chicago, has perfected and put on the market a new telephone switchboard for metallic circuits. This board contains several novel features, all tending to simplify it and reduce the number of parts to a minimum. It does away entirely with all ringing and listening switches, levers, cams, push-buttons and clearing-out drops. The jacks and drops are mounted together, as shown in Fig. 1, and, as no clearing-out drops are required, the switchboard is compact and takes up little space.

Each drop and jack is independent of the others, allowing any one to be removed without disturbing the rest of the switchboard, or disconnecting any line wires, as these are soldered to brackets from which the jacks are readily detachable. The board is claimed to be remarkably fast in operation and free from cross-talk and internal dissensions. The switchboards are all wired for metallic circuits, but can be used for either common return or ground circuits, any one or all on the same board. The construction of the plug makes all ringing and listening connections and clearing-out, without switches, levers and push-buttons.

Fig. 2 shows a diagram of the circuits in ringing, listening and talking positions. No. 1 and No. 2 are full metallic circuits; Nos. 3, 4 and 5 are common return, and No. 6 shows a ground circuit. When the drop falls the operator plugs in as shown in No. 5, allowing lateral pins on plug to make contact with listening terminals of operator's set (D D in Fig. 1). To call a subscriber the plug is pushed in, as shown at No. 3. This pushes the ringing terminals against the line. On removing the hand the plug is pushed out, restoring the through connection, as shown at No 2 and No. 5.





FIGS. 1 AND 2. SIMPLE TELEPHONE SWITCHBOARD.

These switchboards can be built with a cabinet capacity in excess of the number of drops and jacks required, thus providing for future demands from increased business.

Spring Moving and Telephone Service.

The numerous changes in places of business and residence that are made or contemplated at this season of the year in all large towns involve considerable trouble on the part of telephone-exchange managers, who must be prepared for the rush of orders for new service and removal of instruments from abandoned offices. In the principal cities of the country and in many of the smaller places where the use of the telephone is quite general, it is customary for the local company to canvass its subscribers and in advance as possible the number of removals that are likely to take place and the new location of the subscribers. In Chicago, for instance, the following notice was sent to all subscribers of the Chicago Telephone company:

As the majority of the lines of the Chicago telephone exchange system are now connected in underground cables, and the complications in making connections are numerous, also, as there will be a large number of telephones to be moved about May 1st, it is necessary that we have at least 30 days' notice where subscribers desire to have their telephones moved from one office to another.

It will, therefore, vary much expedite this work and avoid interruptions and delays if subscribers will fill out the enclosed blank and return it to us not later than March 25th, that we may execute their orders promptly and with as little interruption to the service as possible.

The order form adopted by the company contains the following provision:

It is agreed that the removal of the telephone, in accordance with this order, shall constitute an express extension of the existing contract between the parties for a period of one year from the date of completion of such removal, and that I am to pay the actual cost of making such removal and connecting up the telephone in the new location.

The Telephone Situation.

By J. J. Nate.

Part IV.

Competition

This element in the work of independent organizations presents a most difficult problem to the promoter. Perhaps this would not be true if the opposition could be dealt with in fair and square competition. Whether it be the policy of the Bell company or not to frighten by misrepresentation and intimidation, those who have experienced the result of competition of whatever character are best prepared to say. I believe, however, from information at hand, that many of the agents and representatives of that corporation are far from honest in their methods of combatting the independent movement; with what degree of success is not so much a question of doubt to-day as it was two years ago. In verification thereof, let us look over the field briefly and ascertain what has been accomplished by the independent telephone companies in three years. In Ohio, Indiana and Illinois the Central Union (Bell) company has practically lost the business of many prominent exchanges. True, in some cities and towns its instruments are still left on the premises of the subscriber, but, as a rule, they are not paid for, or, if paid for, at a rate much below an earning revenue. A movement now on foot for the establishment of an exchange in the city of Indianapolis, if successful, will take from the Central Union Telephone company its most prominent exchange. Victory at Indianapolis implies success at Columbus, Toledo, Cleveland and other large cities within its territory. As the matter stands to-day the company has lost such exchanges as Michigan City, Connersville, Columbus, Crawfordsville, Elkhart, Lafayette, Madison, Munsey, New Albany, Plymouth, Rochester, Rensselaer, Shelbyville, Wabash and Fort Wayne, in addition to the establishment of probably 100 additional exchanges, ranging from 50 to 150 subscribers, many of which were installed and have retained their prestige in opposition to the Bell company from the first.

The Michigan Bell Telephone company has lost such exchanges as Benton Harbor, St. Joseph, Alpena, Grand Rapids, Muskegon, Kalamazoo, Ishpeming, Marquette, Iron Mountain, Escanaba and Detroit, in addition to which are a hundred or more independent exchanges, ranging from 50 to 150 subscribers each, and the coming season will see the installation of independent exchanges at Bay City, Saginaw, Flint, Battle Creek, Jackson and other prominent points.

In the state of Illinois there are over 100 exchanges in satisfactory operation, and all members of the state association. Included in the list are to be found some of the best towns in the state, such, for instance, as Bloomington, Danville, Decatur, Paxton, Watseka, Kankakee, Woodstock, Carthage, Augusta and Cairo.

In Iowa the Bell company has practically lost the business of the most important towns, among which may be mentioned Des Moines, Cedar Rapids,, Decorah, Dubuque, Keokuk, Marshalltown, Oskaloosa, Sioux City, Waverly, Waterloo and Cedar Falls, to say nothing of the loss in toll-line receipts from this and other states.

Wisconsin and Minnesota have also done good work with independent exchanges and immense toll-line mileage. The list includes such points as La Crosse, Prairie du Chien, Winona, Deadwood, Rochester, Owatonna, Wausau, Merrill, Baraboo, Oshkosh, Sheboygan, Grand Rapids, Menomonie, Sparta, Eau Claire and Madison.

These are only a few cities and towns selected from a list of exchanges numbering in total over 1,600 independent exchange companies now in operation. It has been represented that there are over 2,400 independent exchanges now in operation in

this country. It makes little difference, however, as the work accomplished thus far is something truly marvelous, and in a little over three years over 1,600 independent telephone exchanges have been installed in this country, many of which are in successful operation at some of the best points heretofore controlled by the Bell company's exchanges. With few exceptions the independent exchanges are prospering and making money, with a total list of connections numbering at least 250,000 telephones. When we stop to consider that it was several years before the Bell company reached this number in total output, it is really remarkable.

A popular method employed by the Bell company as a means of discouraging prospective investors and subscribers to an exchange system is the reprint of letters received from people who object to two telephone exchanges operating in the same place. I have before me a little pamphlet filled with such letters, issued by the Central Union Telephone company, which I am told is at the present time being largely circulated throughout its territory. I fail utterly to see the advantage gained by this move. No one conversant with the business, not even the opposition, has ever claimed that two exchanges are desirable, and all will admit that one is sufficient, but this admission does not carry with it a statement to the effect that the home exchange should be controlled by the Bell company or its licensees. The pamphlet referred to herein is entitled "A Business Question, Some Facts." This is practically the title appearing on a similar pamphlet issued by the Home Telephone company of Sioux City last June, as an answer to letters written on the subject by citizens of that city, and as it very thoroughly illustrates the situation, I very carefully summed up the result and found that this company had issued a little book which simply gives a list of subscribers after eliminating all names of those subscribers who have in their business places both telephones. The list then follows in the "deadly parallel," and shows that the Bell company had at that time a total of 89 telephones in service in business offices where the Home company's instruments were not in use. The Home company's list under similar conditions shows a total of 340. Why should 340 citizens and interested business men of a community surrender to the wishes of 89 whose interests would seem to lie with the Bell monopoly? How much easier for the 89 to come into the fold, thus making it possible for those who are retaining both 'phones to throw out the Bell instrument and devote their money to the building up of local enterprise!

This matter has become of such serious import that such corporations as the American and United States Express companies have found it desirable to issue instructions to their agents to the effect that it would be well to discontinue the service of one telephone, using their judgment in the matter of selection, preferring the telephone which means the most business. So far as I am able to ascertain, at all points where the home company has the strongest list of subscribers, these agents are retaining the independent company's apparatus. At Jacksonville, Fla., recently a meeting of business men was called for the purpose of "putting a stop to the two-telephone nuisance," and the verdict of that gathering was in substance the abandonment of the Bell instruments in that community altogether, it having been ascertained from two years of actual service that the home company was giving better and more satisfactory service than the Bell in all its 17 years had ever supplied.

I desire to say before concluding this paper that I am not conversant enough with independent telephone exchange work in the extreme eastern and western states to warrant much more in an explanatory way than is very generally known. The following list of cities, taken at random, shows what headway the opposition is making:

Charleston, S. C.	Johnston, Pa.
Richmond, Va	Santa Fe, N. M.
Jacksonville, Fla.	Sacramento, Cal.
Vicksburg, Miss.	York, Pa.
Mobile, Ala.	Fort Wayne, Ind.
San Jose, Cal.	Detroit, Mich.
Portland, Ore.	Grand Rapids, Mich.
Newark, N. J.	St. Louis, Mo.

Nearly all of these exchanges have been in operation for two years, some over three years, and I believe inquiry will show that in every city named the home company has the largest list of paying subscribers.

With such results before us, after three years of remarkable success, I predict that the independent telephone companies of this country are permanently established and will continue to multply and prosper

The Telephone in Dawson City.

Dawson City does not possess all the advantages of metropolitan life, but it proposes to have every facility for quickly transacting business. Consequently a telephone exchange was demanded. An order was placed with the American Electric Telephone company of Chicago for a 100 number board and 100 telephones. The equipment was sent by express to Seattle. The apparatus was packed in long, narrow boxes, two telephones in each package. The switchboard was also built in a long, narrow frame, especially adapted for shipment to the Yukon. The Central Electric company of Chicago furnished supplies for the same order.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

Mayor Doran of St. Paul has signed the franchises granted to the Mississippi Valley Telephone company for a local exchange, the Minnesota Central Telephone company for long-distance service, thus terminating the great fight in St. Paul over telephone competition. The representatives of the Northwestern Telephone Exchange company have been active in opposing the franchises and the new company's friends have also been active. The new companies now have franchises in both Minneapolis and St. Paul, and expect to have exchanges in operation in six months. They claim to have 2,300 subscribers in Minneapolis, against 2,100 now served by the Northwestern, and they will begin work as soon as the frost is out of the ground.

The independent telephone companies will begin work on toll lines from Marshalltown, Ia., to Des Moines, Webster City, Fort Dodge, Story City, Ames and Nevada, Ia., in the early spring.

A telephone exchange will be established in Dunlap, Ia.

The directors of the Iowa Telephone company have decided not to remove their headquarters from Davenport to Des Moines.

A telephone exchange will be installed at Wanamaker, Ia., the Wanamaker and Kellerton Telephone company being formed for that purpose. A toll line will connect with Kellerton also.

Dr. J. C. Hennison has a private telephone system at Bellevue, Ia., to which he will make extensions in the spring.

A telephone system is proposed in Scott County, Minn., to connect a number of the smaller towns with Shakopee, the county seat.

There is talk of a telephone exchange for Luverne, Minn.

The Marshalltown and Boone Telephone company has been incorporated to build a toll line between Marshalltown and Boone, Ia., to connect the independent telephone exchanges in those towns.

P. J. Raarup has completed the toll line of the Wisconsin Valley Telephone company to Bayfield, Wis. The company proposes to put in metallic circuit as rapidly as possible.

The Northwestern Telephone Exchange company is changing over Minneapolis to a metallic system, and is equipping its instruments for the new switchboard which is to be put in this spring. While this change was projected some time ago, it is noticed that work has been much more energetically pushed since a competing company has been admitted to the field.

The Rocky Mountain Bell Telephone company has let contracts for 4,000 poles, to be used in the line to be built between Mullan, Idaho, and Missoula, Mont. The new line is to be completed by July 1st.

The Cumberland Telephone company of Cumberland, Wis., contemplates extending a toll line to Camp Dixon, Timberland and other points.

Arrangements have about been concluded by the Mutual Telephone company of Des Moines, Ia., to install a 200-drop system in Atlantic, Ia.

The Iowa State Senate has passed a bill permitting cities to own and operate telephone systems. It is understood that it was passed to permit the city of Des Moines to purchase the system of the Mutual Telephone company of that city.

C. J. Smallwood is completing arrangements to put in a local telephone system at Worthington, Minn.

The Winona Telephone company of Winona, Minn., has arranged to connect at Witoka, Minn., with the Rushford, Minn., telephone system, and through that city with Decorah, Ia.

Work has been begun on the Union Telephone company's line to connect Wautoma, Wis., with Hancock and other points.

Citizens of La Moure, N. D., rejected the offer of the Midland Telephone company to connect their city with Edgeley, N. D., and towns to the west for a bonus. Instead they will appeal to the Northwestern Telephone Exchange company to give them connection with cities east to the Twin Cities.

The Western Electric Telephone company is working on a toll-line connection through Marshall, Minn.

The Dakota Central Telephone company of Aberdeen, S. D., has been granted toll line connection privileges at Watertown, S. D., and proposes to connect through Watertown with the Minnesota Central Telephone company's system at Ortonville, Minn. Arrangements will also be made to connect with Iowa points.

A telephone line will be built between Bethlehem, Ia., and Russell, in the spring.

Farmers in the vicinity of Whitter, Ia., have formed a telephone company and will connect with Springville and Viola.

The Fort Dodge Telephone company will be formed at Fort Dodge, Ia., to put in a telephone exchange.

An ordinance has been introduced in the council of Duluth, Minn., fixing rates to be charged by the Duluth Telephone company for the remainder of its franchise at $25 per year for business houses and $15 for residences, and providing that the company must supply any instrument ordered within 30 days after the application has been filed. If the company fail to file an acceptance of the ordinance within 10 days after its passage, it is provided that all telephone wires running along any street for more than 500 feet shall be removed to the adjacent alley.

Telephone connection will be made this spring between Langdon, N. D., and Grand Forks.

The Eau Claire Telephone company of Eau Claire, Wis., expects to have 200 instruments in by April 1st. It has orders for 500.

The Chariton and Newbern Telephone company is an applicant for a franchise at Lacona, Ia.

Independent Movement in North Carolina.

H. P. Strause, J. H. Bridgers and F. C. Toepleman of the Henderson Telephone company, Henderson, N. C., have just effected the purchase of the Newbern telephone system. The new company will assume active control of the property on May 1st. Mr. Strause says his company will expend several thousand dollars in improving the property. Mr. Toepleman, general superintendent of the company, will have the property placed in first-class condition at that time. He says the company will put in new switchboards, cables, instruments, etc.; in fact give Newbern an up-to-date telephone system.

The Henderson Telephone company now has exchanges in operation at Henderson, Louisburg, Oxford, Warrenton, Franklinton, Kitterell and Youngsville, with 20 toll stations at intermediate points, connected by upwards of 300 miles of toll line.

Mr. Toepleman hopes by August 1st to have exchanges in operation at Littleton, Weldon, Enfield and Halifax, and to connect them by all metallic lines with plants now in operation.

The officers of the Henderson Telephone company are: President, N. P. Strause; vice-president, T. T. Hicks; secretary, J. H. Bridgers; treasurer and general manager, H. P. Strause, and electrician, F. C. Toepleman.

Southern Telephone News.

Articles were filed with the secretary of state at Frankfort, Ky., March 21st to consolidate into one new corporation the Cumberland Telephone and Telegraph company and the Great Southern Telephone company, the capital stock to be $3,000,000. It is intimated that this is the first step in preparation for a rate war in Kentucky between the new company and the Ohio Valley Telephone company.

At Osceola, Ark., local capitalists have organized a company for the purpose of putting up a local exchange and long-distance lines. The wires are up and the telephones ordered for the exchange, and they will be in operation within 30 days. The company is known as the Osceola Telephone company, and has the following-named officers: President, William J. Driver; general manager, Thomas G. Brewer; secretary and treasurer, R. E. Fletcher.

Interior Telephones.

It would seem as if the use of interior telephones was a novelty in many large cities, judging from the attention that is being paid to the installation of an intercommunicating system in a large establishment in Boston. An eastern paper says: It is announced in Boston that Messrs. Paine, Weber & Co. have just moved into new banking offices at 27 State street, occupying the whole first floor of the new Brazer building, and that "among other conveniences are 22 sets of telephone instruments, comprising the regular local and long-distance sets, the stock exchange telephones and an interior system whereby each desk has telephonic communication with every other desk in the office."

In Chicago the use of telephones for connecting the several departments of large institutions has long since ceased to be a novelty. The Western Electrician introduced one of these systems when it moved into its present quarters, and in many of the large mercantile houses branch exchanges have been established by the Chicago Telephone company. Most of this business, though, is done by the independent companies and has no connection with the exchange system.

COMMUNICATION.

Firman Switchboard Patent Sustained.

To the Editor of the Western Electrician:

The Circuit Court of the United States for the Northern District of California has handed down a decision sustaining the Firman patent, No. 252,570, of January 17, 1882, which is the fundamental multiple switchboard patent. The defendants are the Capital Telephone and Telegraph company and its officers of Sacramento, Cal., who were the first of the opposition concerns to install a multiple switchboard. The court (Judge De Haven) ordered an injunction and an accounting against defendants.

BARTON & BROWN.

Chicago, March 30, 1898.

The Saginaw Valley Telephone company is extending its system in Saginaw, Flint, Bay City and East Bay City. It has put in an underground system and is now putting in new instruments and switchboards. The American Electric Telephone company of Chicago has secured the order for 3,000 new instruments for this system.

Western Electric Fans.

The Western Electric company's desk, bracket and ceiling fan motors are made for 110, 220 and 550 volts, and are so designed that on a 500-volt circuit three 110-volt motors or two 220-volt motors may be operated in series with perfect safety to the motors, and the 500-volt motor can be operated on a 600-volt circuit continuously without injury. All of these motors are wound for three speeds and are made with self-oiling and self-aligning bearings.

On the desk and bracket motors the switch is placed in the base of the motor, whereas in the ceiling fans it is placed in a neat switchbox on the under side of the motor casing. The desk and bracket motors are made in two sizes, the blades measuring 12 and 16 inches in diameter. They have four wings, it having been demonstrated that a four-blade fan is much more efficient than one with six blades. The current consumption of the 12-inch motors is much less than any 16 candle power incandescent lamp on the market, while the current consumption of the 16-inch motors is but a trifle more than that required for the ordinary 16 candle power lamp. The energy required by the 220 and 550-volt motors is practically the same as that required for the 110-volt motors. One very desirable feature is the facility with which the motors can be disconnected from the base and inserted in the bracket. The guard of the motor is made in a most durable manner and is firmly fastened in the motor, which prevents it from jarring. These motors are finished in polished brass, nickel-plate or black enamel without additional charge.

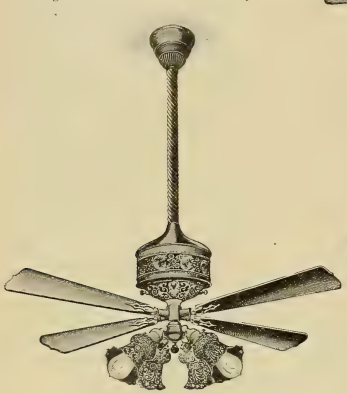


Fig. 3.

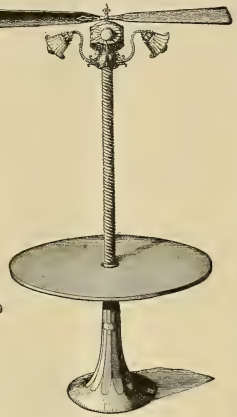

Fig. 4.

WESTERN ELECTRIC FANS.

All ceiling fans are so made that chandelier attachments can be readily put on, every motor being wired ready for the sockets, the lead wires being coiled in the top of the switchbox when not in service. The standard fan consists of four blades, 60 inches in diameter (each 8½ inches wide, and runs at 175 and 18[illegible] revolutions per minute. If desired, motors will be furnished with two blades, running at 210 and 215 revolutions per minute. These fans take but a trifle more current than that required for an ordinary 16 candle power lamp. All motors are furnished with self-oiling and self-aligning bearings and are perfectly balanced. The stems, from which the motors are suspended are usually adapted for 12-foot ceilings. These motors are finished in polished brass, oxidized copper or nickel-plate without additional charge. When ordered, motors will be furnished with one speed, these being made without the switchbox and the speed-controlling parts.

The column fans have but two speeds, 150 and 175 revolutions per minute, and are made with or without polished red birch tables, all metal-work being finished in polished brass or oxidized copper. The motors are furnished with a switch, while the lights are controlled by a switch placed on the under side of the table. The tables can be furnished either square or round and are four feet in diameter.

Special attention is called to the Tuerk alternating-current fan motor, which is furnished with two blades and is designed to be operated on a current of 60, 125 or 140 cycles, at 52 or 104 volts. This motor will be furnished finished in bronze, bowerbarff, nickel, brass or white and gold. All shafts are mounted on self-oiling bearings. A switch is provided for starting and stopping the motors. By a very ingenious device the angle of the blades may be so shifted that the wind may be blown downward towards the floor or upward towards the ceiling. The motors are of the reduction type. A reduction in speed is obtained by the introduction of leather-faced friction wheels, by means of which the motors are rotated at a slower speed than that of the armature; this device enables the use of a highly efficient high-speed, alternating-current motor, obtaining all of the desired results of the slow-speed fan.

Fig. 1.

Fig. 2.

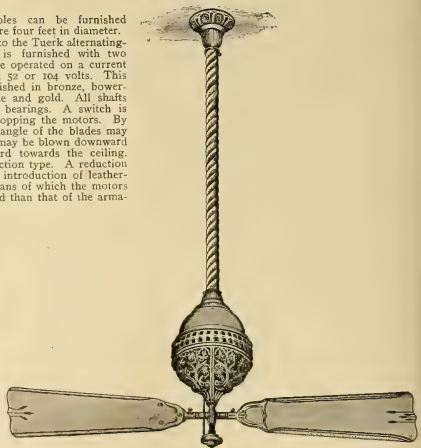

Fig. 5.

WESTERN ELECTRIC FANS.

A handsome catalogue has been issued describing in detail all of these motors and will be furnished upon application.

Referring to the accompanying cuts, Fig. 1 represents a front view of a 16-inch bracket fan motor; Fig. 2, a 12-inch desk fan motor; Fig. 3, ceiling fan with chandelier attachment; Fig. 4, column fan; Fig. 5, Tuerk alternating-current ceiling fan.

The village of Middleport, Niagara County, N. Y., has voted against an electric lighting system.

Municipal Ownership Abroad.

Robert P. Porter, writing in the Sun, says that a former article on the subject of municipal ownership and operation of street railways "has elicited so many letters asking for the entire case in favor of municipal ownership of such undertakings in England" that he prepared the brief statement of facts here given. He says:

"The experience of England up to that time was practically confined to six cities. The street railways of Liverpool had been in possession of the city for about three months, but the results so far were too meager to tabulate, and are not included in these tables. The financial results may be summarized as follows:

POPULATION AND LENGTH OF TRACK.

Name of city or town.	Population. census of 1891.	Length of track, miles.
Glasgow	393,920	77
Huddersfield	100,363	22
Leeds	402,419	28
Sheffield	347,278	10
Plymouth	98,121	4
Blackpool (a)	35,000	5
Totals	1,687,231	150

(a) A summer watering place, like Asbury Park; probably 100,000 population in summer.

PASSENGERS CARRIED AND CAPITAL INVESTED.

Name of city or town.	Number of passengers carried per annum.	Capital expenditure
Glasgow	100,000,000	$4,046,195
Huddersfield	4,308,269	700,000
Leeds	17,000,000 (a)	1,090,000
Sheffield	5,000,000	632,645
Plymouth	1,700,000	250,000
Blackpool	3,500,000 (a)	269,472
Total	131,508,269	$6,988,312

(a) Estimated.

MOTIVE POWER, DATE OF CITY ASSUMING OPERATIONS, RATE OF FARE.

Name of city or town.	Motive power.	Date of city assuming operation.	Rate of fare. cents.
Glasgow	Horse	July 1, 1894	1 to 6
Huddersfield	Horse and steam	1882	2 to 6
Leeds	Horse, steam and electric	1894	2 to 6
Sheffield	Horse and steam	July, 1896	2 to 6
Plymouth	Horse	1892	2 to 6
Blackpool	Electric	1894	4

REVENUE AND EXPENDITURE.

Name of city or town.	Revenue.	Expenditure.
Glasgow	$1,801,807	$1,393,210
Huddersfield	139,490	149,305
Leeds	312,555	285,476
Sheffield	(a)	(a)
Plymouth	37,615	18,566
Blackpool	48,027	45,140

(a) Detailed report for first year not available when I was in Sheffield.

SALARIES, PROFIT AND LOSS.

Name of city or town.	Amount paid in salaries and wages.	Profit and loss.
Glasgow	$632,000	$ 41,798 (a)
Huddersfield	80,000 (b)	306,013 (c)
Leeds	75,000	27,079 (d)
Sheffield		40,000 (e)(f)
Plymouth	13,825	25,000 (g)
Blackpool	15,000 (b)	936 (h)

(a) Annual profit to the common good, $41,798.
(b) Estimated.
(c) Total deficiency, met by the rates.
(d) Profit to the city in 1897 after deducting sinking fund.
(e) Excess of receipts on year's operation.
(f) The old company paid the city $50,000, and the excess of receipts over expenditures here shown is not profit on full investment of $632,645, but on what the plant cost the city, namely,

$133,828. The coming year we shall know more about this investment.
(g) Total deficit.
(h) Profit for the year.

"Having carefully studied the five exhibits, it will be seen that, though they are separate tables, combined they form a nearly complete statement of the results of the street-railway operation of these cities. Do these facts indicate that the English system is any better than the American system of private ownership? It would seem to me, after an examination of the data attainable, that the history and details of the various tramway enterprises in the United Kingdom are neither sufficiently extensive nor sufficiently satisfactory to point conclusively to any decision in favor of municipal operation of such untakings. Similar enterprises, when leased to private companies, both in Manchester and Liverpool, show far better results financially to the municipalities than the examples given above.

"Glasgow shows a profit of $43,793 to the city, with an investment of $4,046,195 (in a horse-car equipment put in during the last half of 1894), when an American firm stood ready to give the city a bonus of $250,000 and install an electric plant free of cost.

Huddersfield, in lamentable efforts to establish municipally operated railways, has muddled away $306,613 in deficits and has $700,000 invested in 22 miles of track.

"Leeds, a city of over 400,000 population, with 22 miles of track, may be said to have done fairly well, because it has not run behind; but does anyone in the United States believe a population of this size can really be served by 22 miles of street railway?

"Sheffield is making a beginning and wisely feeling out after the best system. The excess of receipts for the first year is no indication of what Sheffield will do when she has installed a system of 35 miles. The private company paid $20,000 a year into the city treasury, and has paid off for the city much of the original investment in track. The city thus fell heir to the whole plant for a song, and naturally shows a profit the first year. It would be strange if it did not. Those in control in Sheffield are in no sense prepared to underwrite municipal operation, at least until after an experience of 10 years.

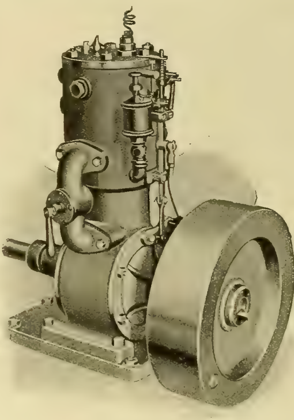
"Plymouth, a small affair, is behind $25,000, while the operation in Blackpool last year yielded a profit to that city of $936.

"Here we have the sum and substance of the municipally operated tramways in the United Kingdom up to date

"As an offset to these cities the attention of municipal-ownership enthusiasts is respectfully invited to the city of Boston, population about the same as that of Glasgow, miles of street railway, 452; Baltimore, population about the same as Leeds, street-railway mileage, 291, and lastly, if there is any city in the United States of 100,000 inhabitants not better supplied with rapid transit than Huddersfield and Leeds or a seaside resort on the Jersey coast that cannot beat Blackpool 10 to 1, I should like to have our municipal-operation friends name it. Here we have a population of 1,087,231, supplied with less miles of track than Washington, D. C., with a population of 250,000. Surely a study of the accompanying table is not calculated to attract the business man, anxious for practical transportation, toward municipal operation as a means of developing rapid transit. And yet we have here positively all the bedrock facts that can be given at the present time. The rest remain locked up in the imagination of those who talk so glibly of the 'strides' municipal ownership and operation are making 'on the other side, you know.'"

Mianus Gas Engine.

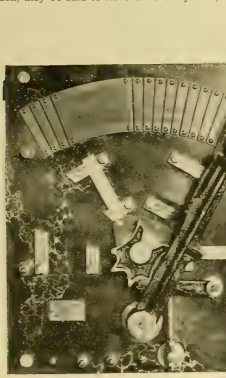
In the accompanying illustration is shown a 2½ horse power Palmer gasoline engine of the marine type, made by the Mianus Electric company of Mianus, Conn. The company manufactures complete gas or gasoline engines of from one to six horse power, both stationary and marine, and can supply the castings, parts and working drawings for the one horse power and 2½ horse power engines, for experimental purposes and for those who wish to construct their own engines. The engine is built on the two-cycle compression type, with an impulse at each revolution of the crank. The company also builds engines of the four-cycle type having an impulse at every other revolution. These engines are readily adapted to motor carriages and are also used for running printing presses and dynamos for electric lighting. They occupy but little space and consume a small quantity of gasoline or gas.



MIANUS GAS ENGINE.

Printing-press Controller.

The motor controller herewith illustrated is especially designed for the operation of printing presses. It is reversible, and is claimed by the manufacturer, the American Rheostat company of Milwaukee, to be an improvement over anything now in the market. This controller has a double-pole, reversing snap switch, which is operated automatically by the throw of the lever, opening the circuit when the lever is brought to central position, and closing the circuit when it is moved backward or forward. With this controller, sparking on the contacts is said to be done away with. The parts are easily accessible and renewable and of first-class material and workmanship. The instrument gives a variation of 12 different speeds on the forward motion and three on the backward motion, allowing the motor to reverse slowly. The company recently installed a large number of these controllers, and they are giving the best of satisfaction, as they prevent any possibility of damage to the motor through the carelessness of the operator.



PRINTING-PRESS CONTROLLER

Cosmopolitan Electric Company's Plans.

Promoters of the Cosmopolitan Electric company of Chicago have taken steps to form a construction company for the purpose of building a central-station and distributing system. The new concern will be known as the Cosmopolitan Construction company. It will be capitalized at $500,000 and will be composed of the men who are interested in the Cosmopolitan Electric company. The latter concern has purchased a site at Grove and Twentieth streets for the power house which it will build. It is now furnishing current from a temporary plant. The management announces that solicitors are now engaged in canvassing for business on the South Side.

The council of Duluth, Minn., has reconsidered its determination to purchase or parallel the electric-light and power plant immediately, and referred the resolution to that effect to a committee with instructions not to report until further orders. The council also voted to force the collection of a judgment for $12,000 which the city held against the street railway if the latter did not in six months accept the terms of paying $1,000 per month.

Telegraphic Communication with Cuba.

The telegraph companies are getting ready to meet the extra demand at southern points which a war with Spain would occasion. Telegraphic facilities will be arranged at Florida that will put Havana in direct communication with all cities in the United States. At the main cable station on the line between Havana and this country, heretofore, all matter from Havana has been relayed, but now single, duplex and quadruplex repeaters will be put in to connect with Havana, thus giving direct communication with all cities in this country. Should an American army be landed in Cuba repeaters will be placed at Havana, and Washington would be in direct touch with the army, in whatever part of the island it might be.

CORRESPONDENCE.

New York Notes.

New York, March 28.—The rapid-transit situation has many elements of interest but does not advance toward a solution. It is reported that the Manhattan Elevated directors have practically decided not to accept terms on the basis of the franchises recently offered the company by the Rapid Transit Commission. The directors claim that the company would be a loser if it undertook the extensions and paid the city the proposed rentals. The commission has its own troubles, too. It held several meetings last week, but as one member is in Europe and the mayor and controller, who are members, are opposed to the policy of the majority, the six votes necessary to adopt the "detailed certificates" of franchises to be presented to the Manhattan company could not be obtained. However, it is stated that the president of the board has in his possession the resignation of Charles Stewart Smith, the member who is now in Europe. The board has the power to fill its own vacancies, and, consequently, Mr. Orr has it in his power to declare Mr. Smith's position on the board vacant, on which the board may elect a successor immediately and in this way obtain the requisite sixth vote. Mr. Orr explained to his colleagues that the resignation had been placed in his hands by Howard C. Smith, to be used if necessary, but that he (Mr. Orr) hoped that as Charles Stewart Smith would be back in New York by April 6th it would be unnecessary to accept the resignation. In the meantime, it is said, irrespective of the Manhattan's action, the commission will proceed with its underground scheme. Every detail preparatory to the advertising of the contract is now nearly finished, and as soon as the order of the Appellate Division is entered steps will be begun to obtain bidders for the work of constructing the tunnel. Mr. Croker has declared war on the Rapid Transit Commission. He says that it is wedded to underground transit and that there is no hope for that system. Tammany, he asserts, would give the people real rapid transit. The mayor takes this view, too, and has expressed his opinion with vigor. Senator Ellsworth has introduced a bill in the State Senate to abolish the existing commission, but it does not appear likely that it will ever become a law.

The government has awarded a contract for more than 100 miles of telegraph cable. This is said to be the largest order ever placed by the government. It is given to the Safety Insulated Wire and Cable

company of this city. Sixty-five miles will be submarine cable and 35 miles will be underground cable. The order is given for the purpose of connecting all the forts and islands in New York harbor, so that in case of war immediate and direct communication can be had between the forts. It is understood that one cable will be laid under the water from Sandy Hook to Fort Hamilton, touching at Fort Wadsworth and Fort Lafayette. Another cable, connecting with this one, will be laid to Governor's Island. At this point the underground cable will come into use and be laid through a certain section not yet selected—it is said to Whitestone and Willett's Point—to connect with Fort Schuyler. As soon as the work is begun, which will be in a few days, it will continue night and day until completed.

A certificate of the lease of the Second Avenue railroad to the Metropolitan Street Railway company has been filed with the secretary of state at Albany. The terms of the lease are that the Metropolitan Street Railway shall control the lines of the Second Avenue company during the unexpired term of the company's charter in consideration of the payment to it of an annual rental of eight per cent. on the par value of its capital stock for the three years commencing March 1, 1898, and nine per cent. yearly for the remainder of the term of the lease. The certificate of lease is signed by Pierre Joy, president, and H. E. Doremus, secretary of the Second Avenue Railroad company, and H. H. Vreeland, president, and Charles E. Warren, secretary of the Metropolitan Street Railway company.

For the public celebration of the new city charter, arranged for May 4th, striking electrical effects are planned. It is proposed to arrange searchlights along Broadway in such a manner that the rays of light from them will extend up perpendicularly. There will be similar displays along important thoroughfares in Brooklyn, and in the other boroughs, and special displays of fireworks will be made at Prospect Park, Central Park, Fort Green, Jamaica, and at points in Richmond and the Bronx not yet decided upon. There will be prizes for street illuminations and house decorations. M. S.

Canadian Intelligence.

Ottawa, March 26.—The Canada General Electric company is supplying three small direct-connected units for the Canadian Pacific Railway steamships on the Stikine River. These machines will be of four kilowatts each, direct-connected to vertical engine of special type, running at 600 revolutions per minute.

There is a good deal of favorable comment on the kindly action of the Royal Electric company of Montreal, in coming to the assistance of the Lachine Rapids company, whose power house was burned during the first part of the present month. The Royal lighted Westmount and Mile End for its competitor, without charge, for several days.

The Electric Reduction company of Buckingham, Que., has placed an order with the Canada Electric company for a 1,000 horse power revolving-field generator, to be used for electrolytic work. The machine will be similar to those installed at Lachine, in the province of Quebec, and also in West Kootenay, B. C., except that the current will be applied at the low potential of 75 volts.

The Welland, Ont., Aqueduct and Power company has been organized with a capital of $25,000, to supply electricity for light, heat and power.

The Toronto Electric Motor company and the Thompson Electric company, Hamilton, have amalgamated, and the change took effect on the 15th inst., under the name of the "Toronto Electric Motor company, limited." The Hamilton factory will be moved to Toronto, and will occupy new buildings, which the company is to furnish by the first of May ensuing. The new shops will be of the most modern type, with traveling cranes, etc. With this change the new company will be in a position to do the heaviest work in power apparatus as well as in arc and incandescent of all kinds.

Engineer Leyden of the Cataract Power company has submitted to the city engineer of Hamilton, Ont., a proposition for running the sewage-disposal works by electric power, but at present it is not known whether his scheme will be adopted.

The Court of Appeals, at Toronto, has given judgment on the appeal by the Toronto Street Railway company against the assessment by the city of the poles, wires and rails of the company for the purposes of taxation. The court decided against the company, confirming the assessment, which had been already confirmed by the county judge. The assessment is for $537,000, which, at the rate of 17 mills, will net the city about $9,000 annually.

A. V. W.

PERSONAL.

G. H. Jay, of the Boston and Great Falls Electric Light and Power company of Great Falls, Mont., is in Chicago.

Reuben Fra[illegible], [illegible], president of the Columbia City Railway company of Washington, died at his residence in that city March 23d, at the age of 60. He was a native of Maryland, but removed to Washington 30 years ago, and had long been identified with the business interests of the city.

Josef Hofmann, the distinguished young pianist, who has created a veritable furore in the musical world, is said to be greatly interested in electrical science, with a turn for mechanical invention also. He has a laboratory in Berlin and has experimented with batteries, telephones and incandescent lamps. A horseless carriage is also building in Berlin from Mr. Hofmann's designs.

A writer in the English Iron and Coal Trades Review makes this interesting comment on a great man's tastes: "The question has sometimes been asked, Why has Sir Henry Bessemer only received a simple knighthood in recognition of his great services to the constructive and manufacturing industry of the country, while Lord Armstrong got a peerage, and Whitworth, Bell and others were honored with baronetcies? I am in a position to state that the proposal was once made to give the late illustrious inventor a peerage, and he declined it. He was a man of simple tastes and habits, and he did not like the idea of accepting a position which, to his mind, would more or less have changed those habits, and placed him in a social stratum to which he had been unaccustomed, and for which he had no taste. But if he had indicated the least disposition to move higher up in the social scale, the chance was open to him, through both Mr. Gladstone and Lord Rosebery."

ELECTRIC LIGHTING.

Williamsport, Md., has voted in favor of lighting the streets by electricity.

The city of Oakland, Md., has voted favorably for the issuance of $25,000 of bonds for the erection of an electric-light plant and the repair of the streets.

The village of Charlotte, near Rochester, N. Y., has decided by a vote of 63 to 24 to establish an electric-light plant at an expense not to exceed $10,000.

The city of Fitzgerald, Ga., has voted for the issuance of bonds amounting to $30,000 for the purpose of constructing waterworks and erecting an electric-light plant.

The city of Ocala, Fla., has recently decided, through its council, to become itself the owner and operator of its electric-lighting plant. The plant now in use is owned by the General Electric company, and the company is willing to dispose of it to the city. But a committee of the council, authorized to employ an expert to examine the condition of the plant, reports unfavorably to the city buying it, and favors the submitting of plans and specifications and the advertising for bids for a new plant.

The Rochester Gas and Electric company has given the Rochester Trust and Safe Deposit company a mortgage of $300,000 to fund the floating debt of the company and for other purposes. The property on which this mortgage is given is already covered by a mortgage of $2,225,000. It covers all the franchises, real estate, gas and electric plants, machinery, apparatus, wires, poles and mains, as well as a number of shares of capital stock in the Brush Electric Light company. The mortgage covers near 19 typewritten pages. It states that at a meeting of the directors held on March 26th the mortgage was agreed upon because "for the purpose of funding the floating debt of the company and of raising money for other corporate purposes, it is advisable to issue bonds of the denomination of $1,000 and numbered from 1 to 300, to bear date March 15, 1898, to be payable March 15, 1918, in gold coin, with interest at five per cent., payable semi-annually on March 15th and September 15th, in each year in gold, the company reserving the right to retire the bonds on March 15, 1902, or on any interest date after that time."

ELECTRIC RAILWAYS.

The Utica (N. Y.) electric railway is to extend its lines to Rome.

The Philadelphia Record says of the proposed $2,000,000 electric railway to Atlantic City, for which surveys have been completed, that it will have as an important feature an elevated steel road across the meadows.

The county commissioners of Cumberland, Md., have granted to the Frostburg and Lonaconing Electric Railway company and the Lonaconing and Westernport Electric company franchises to construct a railway line from Cumberland, Md., to Westernport.

At the recent meeting of the directors of the New England Railroad company the principal matter discussed referred to the extension of the third-rail system to Bristol, Conn., and action toward the furtherance of the project was taken. A director said that the third rail to Bristol will be in operation by June 1st.

American superiority is acknowledged in Korea, where a contract has been awarded by a company formed in the city of Seoul for operating electric street railroads through the principal thoroughfares, with American contractors for its construction. Consul general Horace N. Allen, in his report to the State Department, says that the company known as the Seoul Electric company, has an exclusive franchise, and has paid in about one half of the capital of $300,000. H. Collbran of Denver will construct and equip the road, which will be six miles in length. He has received a cash payment of $100,000 with his contract and the work will be rapidly prosecuted. It is regarded as a profitable enterprise. At present all the financial ventures of importance in Korea are in the hands of Americans.

To all appearances Buffalo is to have a new suburban railroad, as the Buffalo Valley Railroad company has been incorporated to build a line from that city to the village of Java, in Wyoming County, 27 miles away. The company is capitalized at $350,000, divided into 3,500 shares, all of which are taken, and it looks as though the majority of the stock is owned by capitalists who are also the owners of the Pennsylvania Steel company of Steelton, Pa. The route of the proposed road covers the largest tract of land about Buffalo not yet entered by an electric road. It is a rich country, and the line will connect with the Buffalo Railway company's system. The proposed route carries the tracks three-quarters of a mile north of Gardenville, touching the north side of the village of Elma, then, about two miles east of that town, turns from east to south-east and passes about a mile to the west of Marilla, goes through Porterville, Wales Center, Wales Hollow, crosses the Erie county line into Wyoming, passes through Strykersville and ends at Java. George A. and C. W. Ricker are the engineers.

TELEPHONE.

Dr. W. H. Walters is interested in a telephone system to be constructed at Pocomoke City, Md.

Colonel Henry P. Farrow is perfecting plans for the construction of a telephone system from Gainesville to Dahlonega, Ga.

At Moultrie, Ga., J. F. Monk, W. H. Barber and others have received a franchise for the construction of a telephone system and will incorporate a company for the purpose.

POWER TRANSMISSION.

A dispatch from San Francisco says that Prince Poniatowski is at the head of a company which purposes, within a year, to bring at least 10,000 horse power from the waters now running to waste on the western slope of the Sierra Nevada Mountains, in Alpine, Amador and Calaveras counties, by means of an electrical line 110 miles in length, to that city. A system of canals will convey the water to the point of its conversion into electrical power, and the current will be conveyed across San Francisco Bay at an elevation of 325 feet over the shallow waters opposite San Leandro. The cost of the plant is estimated at $1,000,000.

ELECTRICAL SECURITIES.

The Mexican Telegraph company has declared a quarterly dividend of 2½ per cent., payable April 13th.

The Westinghouse Electric and Manufacturing company has declared a dividend of 1¾ per cent. on its preferred stock.

The Edison Electric Illuminating company of Brooklyn has declared a quarterly dividend of 1½ per cent., payable April 15th.

The transfer books of the American Bell Telephone company closed on April 1st, and no more transfers of stock will be made before April 14th, upon which the dividend of $3 a share, payable April 15th, will apply.

The Cincinnati Street Railway company will issue $656,000 new stock, giving the stockholders the privilege of subscribing for the new issue at par. The allotment will be four per cent. The outstanding capital is $16,400,000 and the authorized capital is $18,000,000.

The Consolidated Traction company of New Jersey reports gross earnings for February of $221,646, net earnings of $104,451, fixed charges $115,477 and deficit of $11,026. For the two months ended February 28th the deficit was $4,111, as against $21,332 for the corresponding period of last year.

The North Shore Traction company reports gross earnings for February of $83,856, a decrease of $2,889 as compared with the same month of last year, and net $8,371, a decrease of $23,161. For the two months ended February 28th the gross earnings were $182,720, an increase of $2,270 as compared with the corresponding period of last year, and net $42,852, a decrease of $13,155.

Among the securities recently listed on the Pittsburg Stock Exchange were $9,725,000 of United Traction company 5s, due 1997; $3,000,000 of United Traction company preferred stock and $17,000,000 of United Traction common stock. The par value of the stock is $50. Some trading has been done in the stock since it was placed on the market, the common selling at 9¾ to 10 and the preferred at 40 to 40⅛. The bonds have been traded in moderately at 102 to 102¼. The preferred stock is guaranteed a dividend of five per cent. annually. The company's net earnings for the eight months

ended February 28th were $525,252, against $429,636 last year, an increase of $85,616. The fixed charges for the year 1898 are $386,422, leaving a surplus of $138,829.

The new and uncompleted Columbia and Maryland electric railway, between Baltimore and Washington, known as the Boulevard line, has been sold at auction to the Baltimore Security and Trading company for $450,000. The property was first offered in three divisions, but as the total of the separate bids was only $335,000, the lump sum of $450,000 offered by the Baltimore Security and Trading company was promptly accepted. The road will be reorganized, but it is said will not be operated through to Washington for some time.

The Chicago Metropolitan "L" road reorganization scheme is being discussed, although it is probable that no decision has been arrived at by the committee. No announcement is expected while the Cuban trouble continues. A plan is being considered to reduce the bonds to $10,000,000, lowering the interest rate to four per cent., to make up the scaling of $5,000,000 in preferred stock, and to cut the common stock in half, leaving $7,500,000, and another proposition is to put the interest on a sliding scale, without reducing the bond issue, beginning at four per cent. and increasing it yearly as the road is able to earn the charges.

MISCELLANEOUS.

The American Range Finder company of New York has made an assignment to Charles B. Van Nostrand. The company was incorporated in 1888, with an authorized capital of $500,000, to manufacture the instrument invented by Lieut. Fiske to determine the distance and location of ships at sea. The instrument was adopted by the government for use on the cruisers Chicago and Baltimore.

A man who has "valuable and merchantable thoughts" at night tells a New York Sun reporter how he preserves them. "Formerly, before I went to bed, I used to put my idea pad, with a pencil by it, on a shelf in the adjoining room near a gas jet, left burning low, as I didn't want a light in my sleeping room. When an idea struck me I would get out of bed, go into the next room, turn up the light, make a note of it and go back to bed. But I didn't always do this. I wasn't what you would call lazy, but if it was a very cold night or I was very tired I would say to myself that I thought I could remember that, and so I would take the chances, and then every time I would forget it. I don't know how much money I lost in this way, but a good deal. But now I have a little table at the head of the bed with the pad and pencil on that, and hanging down over it an incandescent electric light. I don't have to get out of bed at all. I have only to turn the key of the shaded light, pick up the pad and jot down the idea. Then I put the pad down on the table again and turn off the light."

TRADE NEWS.

Twelve Westinghouse engines, driving the electric-lighting plants on the new line of Yukon River steamers which are building by the Moran Bros. company at Seattle, Wash., will assist in dispelling the darkness of the long Arctic nights next season.

The Buckeye Electric company is having a good demand from central stations for its special anchored filament 220-volt Buckeye incandescent lamp. The special filament used is said to deliver full 16 candle power for 600 hours, where pressure does not exceed normal. This means profit to both stockholder and patron.

Secretary A. C. Garrison of the Columbia Incandescent Lamp company of St. Louis does not attempt to conceal his gratification at the fact that the business of the company shows an increase of more than 50 per cent. when the first three months of this year are compared with the corresponding period of last year. The Columbia company seems to have no trouble to hold its old business, and is very successful in securing new customers, who are placing large contracts. The trade outlook for this company is most promising.

The Western Electric company has recently opened a branch office at No. 10 Security building, St. Louis, in charge of Mr. Irvine S. Jackson, who will devote his entire attention to the business in that city and the surrounding territory. This office will be furnished with every convenience for meeting the large requirements of the trade, both as regard prompt delivery of goods and satisfactory prices. A stock of goods sufficient to meet the demand will be carried. The policy of opening branch offices is a new one with the Western Electric company, and it may be extended to other cities.

The Electric Ozone syndicate of London announces that it is now prepared to supply commercial ozone generators, made entirely of aluminum. The advantages of these improved apparatus are said to be that the yield of ozone is large (about 100 grammes per horse power hour), that there is no rise of temperature in the ozonizers which may damage them or cause a loss of ozone, that they can be worked in a continuous manner, and can be made of any size to produce from 100 grammes to 1,000 grammes and more per hour. The syndicate asks that those who are desirous of applying ozone in their works may let it know for what purpose and what approximate quality of ozone would be required per hour.

Under the title "Fan Motors," the General Electric company has issued from its press at Schenectady a well illustrated and beautifully printed pamphlet descriptive of its '98 fan motors for alternating and direct curents. In the introduction attention is called to the fact that the General Electric company has manufactured electric fans since the earliest days of the electric motor, and, in its '98 models, embodies the result of its long practical experience. Illustrations are given of the several styles, and each is accompanied by a clearly written and careful description. This pamphlet will be sent to any address on application to any sales office of the company or to the supply department at the principal office at Schenectady.

The Kinloch Telephone company of St. Louis, which is so widely known in telephone circles throughout the country, and which is composed of some of the very best business men of St. Louis, recently closed a yearly contract with the Phœnix Carbon Manufacturing company of that city for batteries and component parts. The Kinloch company from its incipiency determined to use only the very best material in construction and operation. After elaborate tests by the scientific men the company decided that the Phœnix No. 1 carbon porous-cup cell filled all of the requirements, and was the best for its purposes, hence the placing of the contract. The Phœnix Carbon Manufacturing company has made extensive improvements and largely increased the facilities, putting it in position to deliver batteries of this or any other type in any quantities that may be desired. The product in all departments is recognized as the best.

The Metropolitan Construction company is now doing all of the installation work of the Sprague Electric company. The announcement was made in a striking two-color circular by the Sprague company, in which it was pointed out that the Construction company would not only contract for installation and maintenance of Sprague machinery, but of any other machinery as well. The offices of the Consruction company, as well as those of the Sprague company, are in the Commercial Cable building, New York. The officers are W. D. MacQuesten, president and general manager, and Wallace E. Carver, treasurer. The organization of the Sprague Electric company, which was formed by the consolidation of the Interior Conduit and Insulation company and the Sprague Electric Elevator company, is being rapidly perfected. The offices of the company now occupy practically the whole of three floors in the Commercial Cable building. The company recently secured a suite of rooms in the Marquette building, Chicago, which will be in charge of Mr. Millard B. Kitt and Mr. E. B. Kittle, long identified with the company. Well known electrical men and houses are being rapidly secured to represent the Sprague company in various sections of the country, and the organization bids fair to be a remarkably strong one in every way. An advertising and press bureau is one of the new departments of the Sprague company, and it has been installed in a suite of rooms on the nineteenth floor of the Commercial Cable building.

BUSINESS.

The Triumph Electric company of Cincinnati reports a very satisfactory business and points to 95 orders for machines received since January 1st.

Gustave Monrath & Co. of Chicago and New York are doing the wiring for the large electrical plant in the Grand Central railroad depot in New York.

Sipe & Sigler of Cleveland, who are pushing the Willard storage batteries so energetically, have issued a little pamphlet which tells all about the Willard battery, its characteristics, uses and price.

George W. Patterson, the agent for the Gordon-Burnham batteries in the West, calls attention to the merits of these batteries, to the prices that are made on them and to the stock carried in Chicago.

This is the season when fan-motor catalogues flourish. A recent production of this description is that of the Holtzer-Cabot Electric company of Boston. This company manufactures direct-current fans for desks and ceilings. The motors are claimed to be elegant and efficient as well as economical, strong and durable.

The Safety Conduit company of Rankin Station, Pa., states that its "Loricated" electric conduits will be installed in the new United States appraisers' warehouse, New York, also in the Prudential building, Atlanta, Ga., the former building requiring in the neighborhood of 30,000 feet and the latter building over 50,000 feet of iron-armored conduit.

The new Bellfield Hotel, Pittsburg, Pa., will have its own electric light plant, consisting of three Ball engines, built by the Ball Engine company, Erie, Pa., direct-connected to Westinghouse dynamos. McNeil Bros. of Chicago have recently placed in their building a Ball engine, built by the Ball Engine company, Erie, Pa. The engine is direct-connected to a Western Electric company dynamo. The American Bank building, Kansas City, Mo., recently installed an electric plant. Two Ball engines, built by the Ball Engine company, Erie, Pa., direct-connected to the Western Electric company's dynamos, furnish the power.

J. H. Cooke, western representative for the Jandus (formerly Manhattan) enclosed arc lamp, reports inquiry from all parts of his territory from prospective purchasers of enclosed arc lamps. The Jandus 25-inch lamp, burning 150 hours on 12 inches of carbon, is a great favorite. A catalogue is sent on application. A stock of these lamps is carried at Chicago.

Eugene Munsell & Co., importers and wholesale dealers in mica, of 117 and 119 Lake street, Chicago, are sending to the trade a blotter, which is rather artistically gotten up and refers to the rapid growth of their business as being the strongest evidence of the superiority of their mica. They make a specialty of mica for stove and electrical purposes. A funny little man is illustrated as making quick delivery from a great stock of mica in a large city.

The Davis & Egan Machine Tool company of Cincinnati received a number of large orders last week through its office at Berlin, Germany. Among them was one from the Bayreuther Maschinen Fabrik at Bayreuth, near Dusseldorf, for a number of upright drill presses, radial drills, 36-inch lathes and bolt cutters. This customer is said to be the largest builder of electric cranes and hoists in Europe. An order was also received from the Locomotiv Fabrik Maffei at Munich, Germany, for a number of large engine lathes.

The recently patented Newgard waterproof receptacle and globe is finding a large field of usefulness in breweries, paper mills, packing houses, sugar refineries and all other places where moisture or fumes make the insulation of an ordinary lamp socket a difficult proposition. The price of this device is down to a point where it is said to be economy to use it in all places where high insulation is required. The Newgard receptacle and globe is so simple in construction and yet so clever in its conception that it commends itself to everyone at first sight. The Electric Appliance company is always glad to submit a sample of this globe where there is a possibility of its adoption.

The new catalogue of the Electric Gas Lighting company of Boston is an attractive production, with a cover printed in silver-bronze and handsome insert plates in colors. It gives a complete list of house-goods specialties. The well-known Samson battery receives due attention, and the new Nosmas battery is described as "the outcome of numerous inquiries made by electrical contractors for a battery that could be sold at a nominal figure and which will be capable of longer life and more even output than the many cheap carbon-cylinder batteries forced upon an already overcrowded market by American carbon manufacturers." The trade name of this battery can be kept in mind by spelling "Samson" backward.

The General Electric company, in view of the constantly growing demand for apparatus of its manufacture, has decided to make a large increase in its manufacturing facilities. On March 25th the company placed contracts for the construction at its Schenectady works of a new foundry, which will be one of the largest in this country. The present foundry has been for some time entirely inadequate to the demands upon it, and considerable work has been passed on to the admirably equipped foundry which the company has at Lynn. The work to be done has, however, grown even beyond the capacity of both the Lynn and Schenectady foundries, working overtime, and all is now to be concentrated in the new foundry, construction of which is to be begun immediately. The building will be of brick, 500 feet long and 140 feet wide, with an "L" 100 feet by 120 feet.

The Philadelphia Electric Manufacturing company of Philadelphia has been obliged to extend its manufacturing facilities in order to meet the increase of trade which it has been enjoying for some time past. The factory now includes a second floor, from 2011 Market street, extending back to 2010 Commerce street, giving over 4,000 feet of floor space. The company has added a large amount of machinery and experienced help, and is now very busy in preparing for the demand for its ceiling fans, which will embody many excellent points. Particular attention will also be paid to the regular line of work, of arc cut-out boxes and clutches for arc lamps, together with segments in blocks, lamp boxes, magnets, carbon rods and holders, globe nets, carbon cups, etc., which will be manufactured in larger quantities than ever before.

The Marietta Manufacturing company of Marietta, Pa., has now completed its designs of ceiling fans for the coming season and offers them for the consideration of the electrical trade. This concern is under the management of D. H. Kulp, who for many years has been in this line of business, and is proficient in the knowledge of what is necessary to secure the best results in the manufacture of ceiling fans. The fans are built under patents which have been issued to Mr. Kulp. Information can be secured by addressing the company for its new circular matter, which is now ready for distribution, giving full details in regard to its ceiling fan. The Marietta Manufacturing company occupies a large

building, which is fully equipped with modern machinery and tools especially built for the manufacture of the product, and the company guarantees that nothing will be left undone to make its ceiling fans the best in the country.

The Morse Wool Treating company has just completed at Norton, Mass., an extensive plant for purifying wool. The buildings are of a substantial character, entirely fireproof, and were designed and built by the Berlin Iron Bridge company of East Berlin, Conn. The floors throughout the whole plant are of beams and corrugated iron arches, to carry the excessive loads common to warehouse construction. The roofs are of the Berlin Iron Bridge company's patent anti-condensation corrugated iron. The Berlin company has the contract for building a new power house, car barn and steel bridges for the Port Jervis Electric Railway company at Port Jervis, N. Y. The buildings will be of a very substantial character, entirely fireproof, and will also be covered with the company's patent anti-condensation corrugated iron. The bridges are plate-girder type, constructed in a substantial manner for carrying the heaviest loads.

The fiscal year of the Brush Electric company ended January 31st. It reports that it shipped a larger amount of Brush arc apparatus during the last 12 months than in any previous year in its history. Considering the fact that the first Brush arc dynamos were sold in 1880, more than 20 years ago, it is remarkable that the Brush arc system to-day is as successful as ever. A large portion of the business during the last year has been in connection with the sale of large Brush arc dynamos which have given universal satisfaction. Some of the largest electric-light stations in the country have disposed of all of their smaller arc dynamos of different types and adopted the large Brush arc dynamo as their standard. The following list indicates what the Brush company has done in this line since the company began to manufacture these dynamos: Brooklyn (Citizens') 3,360 lights capacity, Brooklyn (Municipal) 1,200, Newark 3,000, Cleveland 1,800, Philadelphia (Brush) 1,500, Philadelphia (Northern) 1,300, Buffalo 4,250, Worcester 1,000, Toronto 900, Quebec 625, Harrisburg 750, Erie 750, Albany 500, Troy 500, Paterson 625, city of Chicago 700, John Wannamaker 625, Carnegie Steel company 500, United States Electric Lighting company, Washington, 1,000; Edison Electric company, New Orleans, La., 2,250; United Electric Light company, Malden, Mass., 720; Manchester Electric company, Manchester, N. H., 500; Reading, Pa., 500; Boston, Mass., 660; Kings County Electric Light and Power company, Brooklyn, N. Y., 625; Cambridge Electric Light and Power company, Cambridge, Mass., 720; Rockford, Ill., 625.

ILLUSTRATED ELECTRICAL PATENT RECORD.

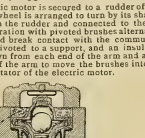
Issued March 22, 1898

600,866. Electrical Alarm Gauge. John Hackney, Norfolk, Va. Application filed June 24, 1897.

An electrically actuated alarm circuit has one pole in electrical connection with the movable hand of the pressure gauge, and the contact point forms the opposite pole of the circuit, and is mounted in the non-conducting sleeve fixed in the gauge-case, so as to be rotated on its own axis and having its recessed end arranged to be projected into or withdrawn from the path of the indicator end of the hand.

600,874. Electrical Device for Propelling Boats. Lyman R. Jones, Boston, Mass. Application filed July 2, 1895.

An electric motor is secured to a rudder of a boat, and a propeller wheel is arranged to turn by its shaft in suitable bearings in the rudder and connected to the electric motor for operation with pivoted brushes alternately arranged to make and break contact with the commutator, an arm centrally pivoted to a support, and an insulated pin projecting down from each end of the arm and adapted in the swinging of the arm to move the brushes into contact with the commutator of the electric motor.



NO. 600,937.

600,890. Trolley Wheel. Elbert R. Robinson, Chicago, Ill. Application filed November 28, 1896.

A flanged grooved wheel having within its peripheral groove a lining with lateral offsets integral with the filling, and the conducting rings at the ends of the hub electrically connected with the offsets.

600,896. Pneumatic Controlling System for Electric Cars. Sidney H. Short, Cleveland, Ohio. Application filed September 20, 1897.

In a pneumatic controlling system for electric cars there is a train of several cars, propelling motors mounted on two or more cars, a motor controller mounted on each motor car, and pneumatically actuated means for simultaneously operating all the controllers throughout the train, and means mounted on each car for controlling the pneumatic actuating means.

600,937. Electric Contact Box. Joseph N. Thomas, Johnstown, Pa. Application filed September 18, 1897.

The method of interrupting an arc which may be formed between the terminals of a switch by the regular current consists in utilizing the heat developed by the arc to melt a fusible portion of the circuit and thus open the circuit to one of the terminals.

NO. 601,023.

600,941. Magnetic Clutch and Power-station System. Bion J. Arnold, Chicago, Ill. Application filed June 20, 1898.

The first claim is appended: The combination of a driving shaft with two power transmitting shafts, said power transmitting shafts located at one end of said driving shaft, one surrounding the other, power transmitters adapted to be operatively connected one with each of said power transmitting shafts, and a driving-connection device associated with each of said shafts whereby either of said power transmitting shafts may be separately and independently connected with the driving shaft.

600,966. Damper Governor. Charles Kummer and Lewis Bertrand, Easton, Pa. Application filed May 4, 1896.

Features of this invention are: an electrically operated damper, a shaft and a damper mounted thereon, a cam plate mounted on the shaft, and magnets mounted adjacent to the shaft, an armature adapted to operate in connection with the magnets, a vibrator adapted to open and close the electrical circuit, a ratchet wheel mounted upon the shaft, a pawl mounted upon the armature and adapted to engage the ratchet wheel, a pawl detent mounted on the casing and adapted to engage the ratchet wheel, brushes adapted to bear upon the plate, binding-screw adapted to engage respectively the brushes, the parts operating in combination with a thermostat, battery and suitable conductors.

600,969. Electric Circuit-closing Device. George Newman, El Paso, Texas. Application filed September 27, 1897.

An electric circuit-closing device having in the face exposed to view and contact a recess, and in the recess a plate of transparent material coated on the under side with luminous or phosphorescent paint, the recess being so configured that the paint is maintained out of contact with the surface of the recess.

600,981. Electrical Measuring Instrument. Edward Weston, Newark, N. J. Application filed December 7, 1897.

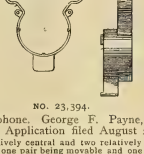
Two current-measuring instruments are attached to a single or common base and have their indicating needles so located with relation to a common scale that independent readings may be taken at the same instant.

600,982. Electrical Measuring Instrument. Edward Weston, Newark, N. J. Application filed December 7, 1897.

This instrument has the movable coil either partially or wholly immersed in a dampening liquid.

600,983. Electrical Measuring Instrument. Edward Weston, Newark, N. J. Application filed December 7, 1897.

The instrument described has its stationary energizing coil wound upon two spools, in combination with a movable coil pivotally supported within the magnetic field between the adjacent ends of the spools and an index hand carried by the shaft of the movable coil, all of the parts being supported or suspended beneath the lid of the inclosing casing.



NO. 23,394.

600,990. Telephone. George F. Payne, Philadelphia, Pa. Application filed August 21, 1897.

Two relatively central and two relatively lateral electrode faces, one pair being movable and one rigid in the supporting frame, granular conducting material situated between the adjacent central and lateral electrode faces, a diaphragm and a positive connection between the two movable electrode faces whereby they are moved synchronously with the diaphragm and so as to simultaneously relax the pressure on one mass of granular material and increase it on the other mass.

600,991. Telephone Transmitter. George F. Payne and William D. Gharky, Philadelphia, Pa. Application filed September 11, 1897.

In a telephone transmitter there is the combination with the electrode box of the two movable electrode buttons and an actuating rod embodying two insulated conductors, one connected with each button.

601,023. Alternating-current Motor. Walter Langdon-Davies, London, England. Application filed November 15, 1897.

An alternating-current motor is described in which the starting coils are of numerous turns and relatively high self-inductance as compared with the running coils and in which a resistance is added at starting to the circuit through the running coils.

601,042. Battery. William Morison, Montclair, N. J. Application filed January 20, 1896.

A battery case is described consisting of a non-conducting material and provided with a holding plate, molded in the same, in combination with a friction spring bolster, the clamp and spring and means to hold the parts together.

601,168. Cluster Fixture for Electric Incandescent Lamps. Nelson Weeks, New York, N. Y. Application filed October 1, 1897.

An incandescent lamp fixture comprises a base having a contracted central portion and a split flanged contracted central portion, contact supports extended through each of the contracted portions, and a cap having a plurality of openings for the insertion of lamp bases to engage with the contacts.

601,172. Portable Camera for Röntgen-ray Photography. Gaston Peguy, Paris, France. Application filed March 23, 1897.

An induction coil and a battery or accumulator, a movable rod having a bevel, and a support carrying a Crookes tube, are employed to form an open circuit, which may be closed by adjusting the rod, the latter having a non-conducting head, which when not in use bears upon the interrupter, and in releasing the latter sets up its vibration.

601,195. High-potential Insulator. John W. Boch, East Liverpool, Ohio. Application filed February 1, 1898.

A high-potential petticoat insulator having a vertical tubular post of porcelain or equivalent material, secured to and supporting the petticoats of the insulator and having its lower end adapted to fit into an opening in the cross-arm and a metal fastening pin in the tubular post.

601,206. Brake for Electric Motor Cars. Patrick B. Hayes and Hugh M. Carbine, Chicago, Ill. Application filed December 23, 1896.

NO. 23,395.

Brake mechanism for motor trucks having duplicate motors is described, including the combination of a wheel-brake mechanism, duplicate auxiliary brake mechanisms for the armature shafts of the motors, and a pair of equalizing levers arranged at opposite ends of the truck and operated from the car platforms, such equalizing levers having operative connection with the wheel-brake mechanism and with the armature-shaft brake mechanisms.

DESIGNS.

28,394. Case for Electrical Measuring Instruments. Edward Weston, Newark, N. J. Application filed February 14, 1898. Term of patent 14 years.

The claim is for the design for a case for an electrical-measuring instrument as here shown.

23,396.

28,395. Electrical Instrument Case. Edward Weston, Newark, N. J. Application filed December 7, 1897. Term of patent 14 years.

Claim is made for the design for an electrical-instrument case as here shown.

28,396. Electrical Instrument Case. Edward Weston, Newark, N. J. Application filed December 7, 1897. Term of patent 14 years.

The design is for an electrical-instrument case as here shown is claimed.

Western Electrician.
EVERY SATURDAY.
Vol. XXII. CHICAGO, APRIL 9, 1898. No. 15

Virginia Hotel Plant.

An attractive electric-light plant in an attractive hotel is shown by the pictures on this page. It is the installation in the Virginia Hotel, at Kush and Ohio streets, and is a model isolated plant for cleanliness, roominess and airiness. The machines are painted white and striped with gold; there is plenty of light, air and head-room; everything is spotlessly clean and the brass railings are polished till they shine. Altogether it is a pleasing plant to look upon. An unusual feature for an isolated plant is the rope drive.

Four tubular boilers, made by Tobin & Hamler, 75 horse power engine and a 100-kilowatt machine by the 150 horse power engine.

The switchboard is ornamented in an unusual manner by two mirror panels, one on each side of the board proper. In the picture a reflection of the larger dynamo is shown in the right-hand mirror. The board is of marble framed in wood, and a brass eagle surmounts the whole with a pilot lamp in its beak. The instruments are of the Western Electric company's type.

From this board current is distributed to about 2,500 incandescent lamps in the hotel and also to two near-by private residences. Several motors are awarded to the Kupferle Bros. Manufacturing company, covers three 150 horse power water-tube boilers with down-draft furnaces, the Paul system of steam heating, two 300 horse power Hoppes feed-water heaters, boiler-feed, house and air pumps, and the complete system of pipework. The steam pressure will be 125 pounds.

The General Electric company secured the contract for electrical equipment, covering three compound Imperial engines of 120 horse power each, directly connected to three 75-kilowatt direct-current dynamos and speeded at 260 revolutions per minute. There will be about 600 16 candle power incandescent

Switchboard. Engines and Dynamos. Hotel Building.

VIRGINIA HOTEL PLANT.

supply steam for the heating, lighting and power plant of the hotel. They are equipped with Murphy furnaces and are 60 inches in diameter and 16 feet long. They supply steam to two Corliss engines, each of which drives a dynamo. The engines were built by Weisel & Vilter of Milwaukee, and are simple engines with Corliss valve gear, one of 75 horse power and the other of double the capacity. Direct rope transmission is used to connect the engines and dynamos, the tightening device being placed between the driving and driven pulley in each unit. Manilla rope seven-eighths of an inch in diameter is used, and there are nine turns on the pulleys of the larger unit and seven on the smaller. The dynamos are direct-current, six-pole, Western Electric machines of 115 volts. A 50-kilowatt machine is driven by the also operated. One, of 15 horse power, drives the machinery in the laundry; another, much smaller, operates a dish-washing machine, while four others are connected to ventilating fans.

Interesting Private Plant in St. Louis.

Contracts have been placed for the mechanical and electrical equipment of the large mercantile building now being erected on the north side of Washington avenue, between Ninth and Tenth streets, St. Louis, by the Commerce Realty company. This building has been leased for 10 years, beginning June 1st next, to the Hargadine-McKittrick Dry Goods company. The contract for steam equipment, which has been

lamps in the building and 400 long-burning enclosed arc lamps. The electrical plant will also furnish current for driving the entire elevator plant, the contract for which has been awarded to the Sprague Electric company of New York. This contract covers two passenger elevators, six freight elevators, one dumb-waiter and one ash-hoist. The distribution will be on the 220-volt two-wire system for all the different kinds of service. The elevators are to be run from the same generator units as the lighting system.

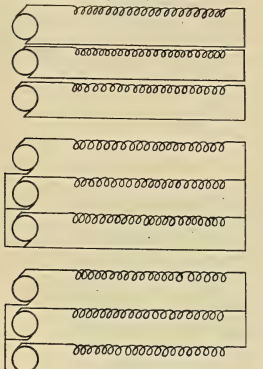
This installation represents a distinct advance in St. Louis in modern installations of this character, and its performance will be watched with interest. Eames & Young are the architects and have associated Bryan & Humphrey with them as consulting engineers.

Three-phase Machinery.

By William Mayo Venable.

The object of this paper is to present in simple form some facts about polyphase circuits, so that they can be understood by those electricians who have not the time or inclination to study the subject more thoroughly. The curves given, when not diagrams merely, show the results of actual tests on machines. However, they are introduced, not as data, but as illustrations.

If three alternating-current generators, supplying three separate circuits, as in Fig. 1, are connected together at one terminal only, the operation of the machines will not be affected. Such a connection merely brings the three terminals to a common potential, and does not affect the difference of potential between the two terminals of any one machine. There will, therefore, be but little effect on the operation of the machines if a common wire is run for all, as in Fig. 2. Now, if we can so arrange our circuits, and so construct our dynamos, that there will never



FIGS. 1, 2 AND 3. THREE-PHASE MACHINERY.

be any current in the common-return wire, we can dispense with that wire. This condition is fulfilled when the currents in the three remaining wires are 120 degrees apart in phase and equal in intensity.

Fig. 4 represents three sine curves 120 degrees apart. From this figure it is readily seen that the algebraic sum of the currents at any instant is zero. We have, then, the arrangement shown in Fig 3, and we need to run three wires only, instead of six, assuming that the loads in the three branches are equal, so as to eliminate any trouble from unequal losses in the different branches. The easiest way to keep the machines 120 degrees apart in phase is to make three machines in one, that is, to put three windings on one armature. Such machines are called three-phase machines.

A simple one can be made of a Thomson-Houston arc dynamo by bringing the terminal wires to col-

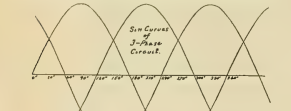


FIG. 4. THREE-PHASE MACHINERY.

lector rings instead of to the three commutator segments. The fields would have to be separately excited. Fig. 5 is a diagram of such a winding. The number of poles can, of course, be increased, just as in an ordinary alternator, increasing the frequency of alternations.

Having a machine thus wound with three coils, there are two simple ways of connecting the coils. One of these, known as the star connection, is shown in Fig. 6; the other, known as the mesh connection, is shown in Fig 7. In the mesh connection the potential between any two lines is the potential developed by one coil only. This connection is used when current for light or both light and power is to be supplied from the same generator, as it is not so apt to become unbalanced as the star connection. When the coils are connected in the star connection the potential developed between terminals is some what greater than in the mesh connection. This arrangement is used where the dynamo supplies current for power purposes only.

Thus a three phase circuit is simply an arrangement of alternating circuits, and follows the same laws as ordinary alternating circuits. But on account of the peculiar arrangement we are able to obtain phenomena which cannot be obtained with simple alternating currents. We are able to make a self-starting motor, without collector rings or movable contacts of any kind, thus getting rid of one of the most objectionable features of other types of dynamo-electric machines.

If two coils of wire are set at right angles to each other, with the intersection of their planes along a common diameter, as in Fig. 8, and these coils are supplied with alternating currents of the same periodicity, but 90 degrees apart in phase, the re-

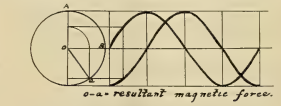

FIG. 9. THREE-PHASE MACHINERY.

sultant magnetic effect is similar to that of a magnet rotated about an axis perpendicular to its magnetism. In Fig. 9 the radius of the circle represents the resultant magnetic force, and rotates once each cycle, or complete double alternation. Now if we have three coils 120 degrees apart in phase, we have to compound three curves instead of two. The result is shown in Figs. 10 and 11. A ring of iron passed through the coils A, B and C would have a tendency to rotate. This tendency is greatly increased by winding the ring in a manner similar to the winding of the coils. Motors built on this principle are called rotary-field or induction motors.

The appearance of induction motors is familiar to all readers of electrical journals. The magnetic parts, both the stationary and rotating portions, are

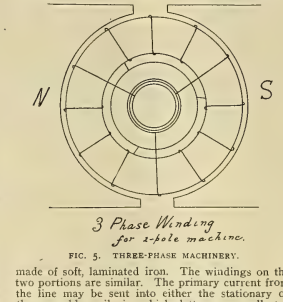

FIG. 5. THREE-PHASE MACHINERY.

made of soft, laminated iron. The windings on the two portions are similar. The primary current from the line may be sent into either the stationary or the movable coil, in which latter case collector rings must be provided. Sometimes the motor is made to perform as both motor and transformer, as in the railroad now being installed in Varse, Italy.

In its applications the inductor motor is as flexible, as simple, as easily controlled and as reliable as the continuous-current motor. It has certain advantages not possessed by the continuous-current machine, notably the absence of a commutator or sliding contact of any kind. Its use is, however, restricted to those localities where current can be obtained from either a two-phase, a three-phase or a monocyclic generator.

The starting torque of a rotary-field motor can be made very large if desirable, but it is usually slightly less than that of continuous-current motors of the same capacity, so that the motor may be most efficient when running at full speed. In stationary motors a resistance is frequently inserted in the secondary circuit during starting, but short-circuited when the machine has attained full speed.

The curves, Figs. 12, 13 and 14, show the general

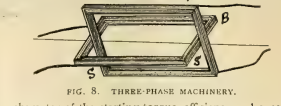

FIG. 8. THREE-PHASE MACHINERY.

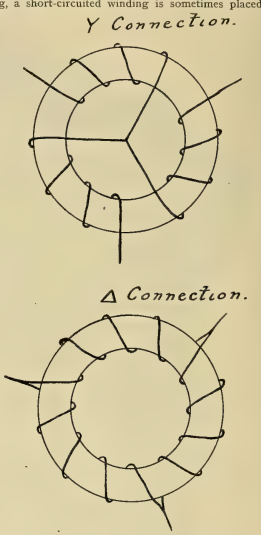
character of the starting torque, efficiency and speed curves of certain experimental three-phase motors. These curves show the character of the machine only. They do not represent the excellence of any machines now on the market. The speed regulation of these machines is particularly interesting to the practical man.

The dynamo for three-phase transmission may be simply an ordinary alternator with a special armature. This armature has three sets of coils, 120 degrees apart in phase, and three collector rings. It is possible to compound these machines for constant potential, but for purposes of power transmission it is not necessary.

The self-starting synchronous motor is a motor which starts itself by induction, and runs at constant speed, with a separately excited field, when once started. The speed of a synchronous motor is determined by the number of alternations per second supplied by the generator. The motor itself is in all respects like the generator, and could be used as a generator if desired. In operating synchronous motors it is important to have the proper relation between the field strengths of the generator and the motors. If the field is too weak in the motor, the machine will take excessive current without developing the corresponding amount of power, but it will not change its speed as a continuous-current machine would, but will suddenly stop when sufficiently overloaded. If the field in the motor is too strong the machine will develop a potential higher than that supplied by the generator, and will stop when overloaded, because sufficient power cannot be given to it. If the field strengths of the two machines are properly proportioned, the synchronous motor will carry its load and maintain an absolutely uniform speed. It is also very efficient.

In order to make synchronous motors self-starting, a short-circuited winding is sometimes placed



FIGS. 6 AND 7. THREE-PHASE MACHINERY.

in slots in the pole-pieces. Fig. 15 is a diagram of this winding.

Another important type of three-phase machine is the three-phase to continuous-current transformer. It consists of an ordinary railway generator, with collector rings connected to three points in the armature winding. The arrangement is shown in Fig. 16. The machine is now capable of running either as a synchronous three-phase motor or as a railway generator. Now, it is evident that if the field switch at the commutator end is left closed, at the moment the machine comes into phase, a continuous current will be generated at the commutator, and the field will become excited (Fig. 17). The motor will then run synchronously, taking alternating current at the collector rings and developing continuous current at the commutator. Such machines already have wide application in street-railway work.

If the machine builds up with the polarity reversed from that usually employed, it can be reversed by opening the field switch long enough for the armature to drop behind a half of a revolution, and then closing it again.

The following tests were made on four-pole, 100-kilowatt machines, one of which was fitted with three collector rings instead of its commutator, while the other was provided with both commutator and collector rings, the latter being fastened on the shaft where the pulley is usually placed.

The machines were run at much higher speed than is employed with direct-current generators of the same size and style, in order to obtain the proper frequency of alternations. This made it necessary to weaken the fields in order to get the proper voltage, and the iron was not sufficiently saturated. The first tests were made to determine the relations of the strength of field, the load, the voltage at the

commutator, and the voltage at the collector rings. The frames, spools and armature windings of the two machines were exactly alike. The curves, Fig. 18, show the relation between the electromotive force at the brushes of the transformer and the ratio of the field strengths of the transformer and the generator. The voltage at the collector rings was kept constant while making a test.

If both the voltage at the collector rings and that at the commutator are to be kept constant, the strength of the transformer field must be increased, as shown in Fig. 19.

The effect of shifting the brushes is represented in Fig. 20. It is very important that the brushes be properly set, or sparking will occur, but, once set, a wide variation in load is practicable.

The induction motor can be operated at any number of alternations per second which may be required, but the practice is usually to employ a somewhat lower frequency than that hitherto used in alternating-current electric lighting, on account of advantages to be gained in the motors. A lower periodicity necessitates changes in the construction of transformers, in order to secure the same economy. A lower periodicity means that more material must be used, just as a slower speed on a dynamo means a greater weight in order to obtain the same output.

When the periodicity is reduced considerably it becomes very difficult to operate arc lamps on an alternating circuit, and if it is still more reduced the pulsations in current can be noticed in an incandescent lamp.

In addition to the advantages gained in the use of induction motors, the three-phase system has also the advantage of a saving in the amount of copper re-

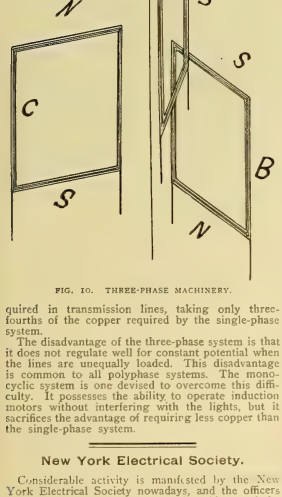


FIG. 10. THREE-PHASE MACHINERY.

quired in transmission lines, taking only three-fourths of the copper required by the single-phase system.

The disadvantage of the three-phase system is that it does not regulate well for constant potential when the lines are unequally loaded. This disadvantage is common to all polyphase systems. The monocyclic system is one devised to overcome this difficulty. It possesses the ability to operate induction motors without interfering with the lights, but it sacrifices the advantage of requiring less copper than the single-phase system.

New York Electrical Society.

Considerable activity is manifested by the New York Electrical Society nowadays, and the officers are to be congratulated upon this evidence of the success attending their management. An indication of the appreciation that is felt for these efforts is the remarkable increase in membership of late. At the meeting on March 30th, for instance, the following-named gentlemen were admitted to membership:

W. C. Broadhurst.	Jens Skougaard.
H. M. Lamont.	E. V. Porter.
G. Morris Haskell.	C. D. Warner.
Edwin H. Daly.	S. Glover Way.
Gustavo Lobo.	Harold Briesen.

Biography of a Piece of Copper Wire.[1]

By CHANNING T. GAGE.

I desire to give you as briefly as possible an outline of the various processes through which the bare and insulated copper wire of commerce passes, from its crude natural condition to some of the numerous forms in which it becomes useful to man.

Copper occurs in this country in two distinct conditions. In Montana and Arizona there are enormous deposits of copper ore in the form of sulphides, oxides or carbonates, though it is believed that the two latter are a result of the decomposition of the former.

This ore seems to have been projected upward

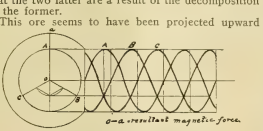

FIG. 11. THREE-PHASE MACHINERY.

in a semi-fluid state from the interior of the earth, and through great fissures or cracks in the earth's crust, after violent volcanic action, which had tilted the rocks from a horizontal to an angular or nearly perpendicular position. These ores require a very complex system of treatment to eliminate impurities and reduce them to metallic copper.

The second class of copper ores is found on the south shore of Lake Superior and constitutes the only natural deposit of ore in the world containing pure metallic copper free from all chemical impurities. There we find it in all forms and sizes, from particles as fine as flour to masses weighing hundreds of tons; from the Phœnix mine there was taken out a single mass weighing 500 tons.

The Arizona ore is the richest of any produced in this country, containing about 10 per cent. of copper; that in Montana contains about seven per cent., while the conglomerate rock of Lake Superior contains from one to four per cent., and the amygdaloid rock from one-half to one per cent. The greater expense involved in reducing and purifying the western ores practically balances their greater richness, so that the Lake Superior mines are able to produce the purest and cheapest copper in the world.

The Lake Superior copper deposits exist in the greatest abundance on that geological freak, Keweenaw Point, jutting out into the waters of the lake for about 60 miles in a northeasterly direction from the upper peninsula of Michigan. Here we find extending nearly the entire length of the peninsula outcroppings of copper-bearing rock, and the same strata have been traced far to the southwest through Michigan and Wisconsin.

Copper ore occurs in two distinct forms in parallel veins on Keweenaw Point.

First—The so-called "ash-beds," or amygdaloidal ore. In this the containing rock is of a soft, easily crushed material, of igneous origin, somewhat similar to lava, and in the porous cells of which the metallic copper is deposited in fine particles. This ore is easily worked, and, as in the Atlantic mine, can be made to pay well, even when containing but three-quarters of one per cent. of metallic copper.

Second—The conglomerate beds, in which the great fissures in the original rocks were filled with a sort of pudding stone, in which the cementing material has been partially displaced by metallic copper, tough and fibrous, binding together the pebbles and stones in masses almost impossible to crush.

Geologists differ somewhat as to the exact process by which this metallic copper was deposited, but many think that these fissures were originally filled with lava in the one case, or the conglomerate mixture in the other, by the action of intense heat and pressure from below. This cooled and subsequently, through a period of time possibly extending through ages, a solution of some copper salt gradually percolated through the fissures, and by a sort of electro-chemical action deposited metallic copper in place of the original cementing material. Thus we find in these conglomerate veins copper in every conceivable form—in little nuggets, thin leaves and threads, and great, irregular, jagged masses.

For the purpose of this paper I will consider that our piece of copper wire originally formed a part of one of these masses and was taken from the famous Calumet and Hecla mine.

There is positive evidence that these copper deposits were once worked by aboriginal miners long before the period of the present race of American Indians.

It is stated that on the site of the Calumet and Hecla mine an Irishman had located his cabin, and one day his pig, in exploring for edible roots, accidentally tumbled into one of these ancient excavations. On getting the pig out it was found to be well covered with a green mud, giving evidence of the presence of copper ore. The mud and rubbish were cleared away and a fine deposit of rich conglomerate rock was uncovered.

These deposits occur in so-called chimneys or strata of copper-bearing rock, alternating with strata of non-metallic rock. In this mine the chimney is about 13 feet in thickness and extends a distance of nearly three miles, of equal richness, and all controlled by this company. They had, in 1891, 17 shafts following the dip of the vein at an angle of about 37 degrees, to a depth of 3,800 feet. Some of these shafts are now down over a mile.

Their latest shaft, recently completed and called the Whiting mine, has three compartments, two for hoisting rock and one for pipes, wires, etc. This shaft extends down vertically 5,500 feet, thus tapping the vein of ore at a point nearly 7,000 feet from the surface of the ground, measured on the dip of the vein. Through this vertical shaft, steel hoisting ropes, 2¼ inches in diameter, lift to the surface 20,000 pounds of ore at a time. At this great depth the ore shows no sign of failing in quality or quantity, and to secure it becomes only a question of expense in hoisting it to the surface.

After the ore has been removed from the mine, and, to a certain extent, sorted, it is sent to the stampmills, where immense stamps crush it to small particles and large quantities of running water wash away most of the pulverized rock, the heavier copper settling to the bottom. This residue contains from 40 to 80 per cent. of copper and is next sent to the smelter. There it is placed in a large reverberatory furnace in 10-ton charges. By treatment with the proper flux and the intense heat of the

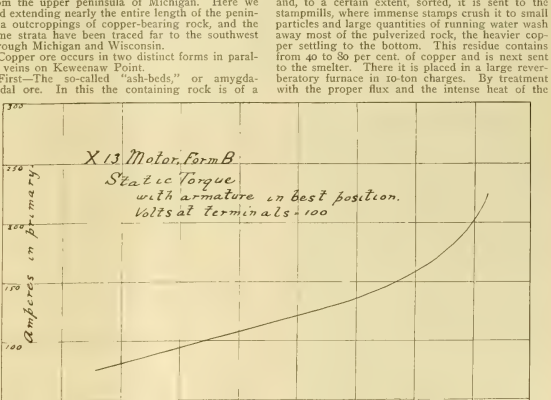

FIG. 12. THREE-PHASE MACHINERY.

furnace, the last vestige of rock and sand is removed and the pure metallic copper is cast into ingots weighing from 250 to 300 pounds each. These ingots are then shipped to the numerous wire mills and enter on the final process of conversion into wire.

At the wire mills the ingots are pushed into one end of a furnace and are gradually brought to a white heat by the time they reach the other end. There a workman reaches in with a pair of immense swinging tongs and starts one of these ingots down the incline and through the first pair of rolls, by which it is somewhat reduced in size and in

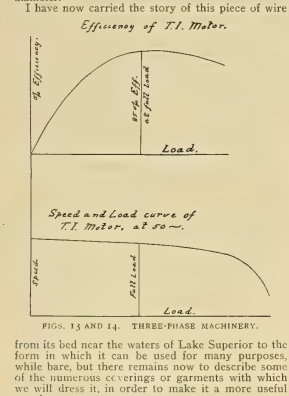
[1] Read before the Chicago Electrical Association, March 15, 1898.

creased in length. Other pairs of rolls are in line just ahead, and the hot ingot passes rapidly through these, until it is reduced to the appearance of a long, fiery snake, writhing and coiling about the great iron floors yet guided through the proper openings by hands that are quick and sure. After passing the last roll, it finally shoots at lightning speed into a revolving reel, into which it is coiled, then removed and hung up to cool. It is now a "rod," about three-eighths inch in diameter and the coil is known in the mill as a "bundle of rods." It is covered with a coating of black copper oxide, and in this condition looks like iron wire, and must be cleaned. It is dipped in an acid bath, where the oxide is dissolved, and the bundle comes out, clean, bright, reddish-yellow copper. This is thoroughly washed and goes to the drawing room. Here one end is tapered and passed through a "die" or block of steel with a tapering hole in it; the end is fastened to a revolving drum and the wire drawn through the die and reeled on the drum. This operation is repeated, each time reducing the size and lengthening the wire, until the desired size is reached. This also thoroughly hardens the wire and makes what we call hard-drawn copper, such as trolley and telephone wire.

For further drawing, or to make soft-drawn copper, the coils are annealed or subjected to a high temperature for a certain length of time, and after cooling the copper is again soft and pliable. This drawing process may be continued until our original ingot, about three feet long, has been lengthened to a piece of No. 36 telephone magnet wire 750 miles in length.

These finer sizes are drawn by specially arranged machinery through dies made from the hardest of precious stones. It is possible by this means to produce an almost invisible wire .001 of an inch in diameter.

I have now carried the story of this piece of wire



FIGS. 13 AND 14. THREE-PHASE MACHINERY.

from its bed near the waters of Lake Superior to the form in which it can be used for many purposes, while bare, but there remains now to describe some of the numerous coverings or garments with which we will dress it, in order to make it a more useful member to society.

First, we will take the simple magnet wire—just a little round wire with a half dozen parallel threads of cotton wound about it.

Remember the great cotton plantations in the South, with the negroes cultivating and picking it; the cotton bolls go to the gin, where the seeds are separated; then go to the baling press, and then to the mammoth mills of New England, where the white threads are spun out by automatic machinery.

In the wire mill this thread is wound on special spools and these are in turn swung around and around our piece of copper wire, held firmly in place, until a beautifully smooth, white covering just hides the wire from sight. One layer of cotton makes our single cotton-covered magnet wire, and a second set of spools following the first winds another set of threads in the opposite direction, and we have double cotton covered magnet wire.

Now bring from China the choicest product of her silkworms, spun into threads of finest quality, and, putting this through the same process, we have silk covered magnet wire, which you all know is such an important factor in telephone construction.

Think for a moment, also, of what might be the present development (or lack of it) of all the varieties of electrical machinery without magnet wire—generators, motors, transformers, voltmeters, ammeters, wattmeters, telephone and telegraph instruments, electric bell and alarms, arc lamps, etc.

When Prof Morse made his first experiments in telegraphy he secured a great length of wire in his laboratory by carrying it around the room back and forth on pegs, and his crude magnet was made by coating a piece of horseshoe-shaped iron with varnish and winding this with bare copper wire, the turns spaced just far enough apart to prevent touching. In the next electro-magnets made by his partner, Alfred Vail, they used the only covered wire then known, viz., that used by milliners for stiffening hats and bonnet rims.

Now, step over into the oil fields of Pennsylvania and see the great tanks full of black, fragrant crude oil; follow it to the refinery and watch the process of distillation and cleansing, until, as one product, you see a clear, white, semi-transparent substance called paraffine, nearly impervious to water, yet easily melted. Wind two layers of heavy cotton over a small wire, at the same time saturating it thoroughly with this warm paraffine, and you have the common annunciator wire, with the aid of which half the doorbells in the city are made to jingle at the push of a button.

Fig. 15.

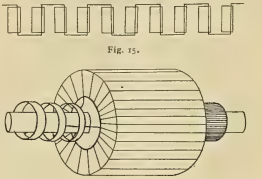


Fig. 16.

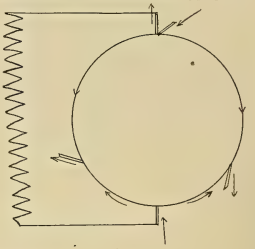

Fig. 17.

THREE-PHASE MACHINERY.

Office wire is made of the same materials, but the cotton is braided on instead of being wound and is made heavier.

Next we will journey to distant Poland and bring back some of that peculiar bituminous deposit called mineral wax or ozokerite, and, combining it with other suitable materials, we will thoroughly saturate the two or three cotton braids which we have woven on another piece of wire, and we will have the well-known weatherproof wire, of which immense quantities are now used for the outside lines of electric-light and street-railway plants. It is also superseding annunciator wire for interior bell and signal work.

Now travel with me once more to still another foreign land, and deep in the forests of South America we will find the wonderful india-rubber tree. Watch a swarthy native as he slashes into the bark with his knife, and there slowly oozes out a milky white fluid, which he deftly catches in a rude basin. This is allowed to stand until upon its surface rises a creamy layer, which he gathers on a clay ball attached to the end of a stick and dries over a fire of leaves and twigs. This rough ball gradually

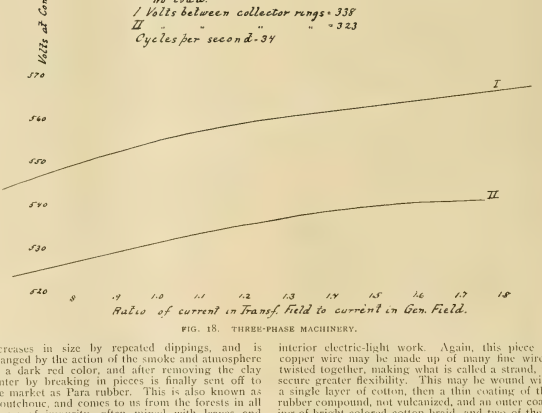

FIG. 18. THREE-PHASE MACHINERY.

thin disks and dried in the air, which changes it to a dark brown color by oxidation.

This brings us to the subject of rubber-covered wire, a product which has during the last few years assisted greatly in the progress of electrical development. When we stop to think of it, is it not one of the wonderful things to consider in nature that this one material possesses the peculiar properties necessary for electrical uses, viz., a perfect insulator, thoroughly flexible, yet capable of receiving treatment that will harden it almost to the texture of ivory and still retain its wonderful insulating properties!

The pure rubber would be almost valueless for many purposes, except for this property of being hardened or vulcanized by the action of sulphur and heat.

That was a wonderful discovery of Mr. Goodyear, which, though called accidental, must have been a part of the Creator's plan for the development of our modern civilization.

Now comes in play the art of the maker of rubber-insulated wire. Pure rubber used as an insulator gradually deteriorates and loses its insulating qualities; therefore he skillfully mingles with it various materials in just the right proportion, and the mixture is then applied to the wire (which has previously been well tinned), with the aid of specially designed machinery, and is then taken to the vulcanizing ovens, where just the necessary degree of heat is applied, and the resulting product is an insulating covering for the wire which will maintain its value as an insulator for many years without change.

Now, taking this plain rubber-covered wire as a basis, look for a moment at its various uses. Covered with a cotton braid, usually saturated with a protective compound, we have the ordinary wire for interior electric-light work. Again, this piece of copper wire may be made up of many fine wires, twisted together, making what is called a strand, to secure greater flexibility. This may be wound with a single layer of cotton, then a thin coating of the rubber compound, not vulcanized, and an outer coating of bright-colored cotton braid, and two of these twisted together form the ordinary commercial lamp cord. This is now being superseded very largely by a similar product made with vulcanized rubber.

We will now take another length of the plain rubber-insulated wire, wind about it spirally a coating of adhesive tape, and pass it slowly through the lead press. By this machine a smooth uniform coating of lead is placed over the tape, making the well-

know lead-encased cables, used so largely for underground service. Pure lead is too soft to withstand the friction of drawing the cable into ducts, so two or three per cent. of tin is added to the lead, which hardens it somewhat, but not enough to permit cracking when bent. This lead covering acts as a mechanical protection to the rubber and adds very materially to its life.

Another class of cables are made, in which the rubber is replaced by a saturated paper insulation. These cables have a very high insulation resistance as long as the lead covering remains intact, but as soon as the lead becomes perforated from any cause, mechanical, chemical or electrical, they must be replaced. For underground telephone lines the paper-insulated cables have a special value, and are extensively used in all the large cities. Usually 50, 75 of 100 pairs of wires are bunched together and a lead casing is placed over all.

For submarine cables, crossing rivers, harbors, etc., the lead-encased rubber cable is covered with a layer of jute and then an armor of galvanized iron wires is laid on spirally for protection against boats and anchors.

For ocean cables there is used as an insulator a gummy material gnown as gutta-percha. It is gathered from tropical trees, similar to caoutchoue, but it has certain properties from an electrical standpoint making it peculiarly adapted for use in submarine work. These cables are not lead encased, but usually have three layers of armoring laid on in reverse directions and well juted between.

The first submarine cable ever laid was in Calcutta in 1839, across the Hugli River; the copper wire was insulated with cotton thread with pitch and tar, and did very good service for a long time.

From that small beginning submarine cables have increased in numbers, until they form a veritable network, encircling the earth in all directions.

Patents and Trademarks.

[From the Washington correspondent of the Western Electrician.]

More important measures for altering the patent laws and the laws governing the registration of trademarks are pending in the present Congress than have been considered in any other within the last quarter of a century. Among the more recent measures is one introduced in the House by Representative Maxwell to amend the Revised Statutes relating to patents. It is now under consideration in the House committee on patents. The bill provides that section 4884 be amended so that every patent shall contain a short title or description of the invention or discovery, correctly indicating its nature and design, and a grant to the patentee, his heirs or assigns, for the term of 17 years, of the exclusive right to make, use and vend the invention or discovery throughout the United States, referring to the specifications for the particulars thereof. A copy of the specifications and drawings shall be annexed to the patent and be a part thereof. The provision is made that no patent shall be granted in any case where the alleged invention is a mere rearrangement or variance in constructive devices and details of an invention already known. It is further provided that where a combination of such details and devices produces a new and useful result, not caused by the separate action of either or all of the old devices and details, but due to the cooperation or reciprocal action of the combined devices and details, it may, if of sufficient utility, be subject to a patent.

It is proposed to amend section 4886 of the Revised Statutes, as amended by the act of March 3, 1897, so that any person who has invented or discovered any new and useful art, machine, manufacture, or composition, or any new and useful improvement thereof not known or used by others in this country, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof, and not in public use or on sale for more than six months prior to his application, may secure a patent, if the device be of sufficient utility, unless it is proved to have been abandoned by a failure to make application in six months, in which case no patent shall issue.

The third section of the bill is to amend section 4919, and provides that damages for the infringement of any valid patent may be recovered in a civil action by anyone interested as patentee, assignee or grantee, but before an action can be maintained against one who has purchased and used in good faith a machine, instrument, or composition so patented, the patentee or his assignee who claims an infringement must recover a judgment against the party guilty of such alleged infringement, and establish the same. Whenever in such action a verdict is rendered for the plaintiff the court may render judgment thereon for any sum within the amount found by the verdict as actual damages, together with the costs, but not for damages in excess of the verdict.

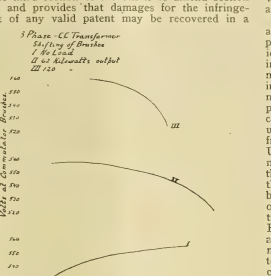

FIG. 20. THREE-PHASE MACHINERY.

A bill has been introduced in the Senate by Senator Platt of Connecticut providing for an increase in the working force of the Patent Office in order to facilitate the work of the office, which is greatly in arrears. The bill provides that for the purpose of determining with more readiness and accuracy the novelty of inventions for which applications for letters-patent are or may be filed in the Patent Office, and to prevent the issuance of letters patent of the United States for inventions which are not new, the commissioner of patents be authorized and directed to revise and perfect the classification by subjects-matter of all letters patent and printed publications in the United States Patent Office which constitute the field of search in the examination as to the novelty of invention for which applications for patents are or may be filed.

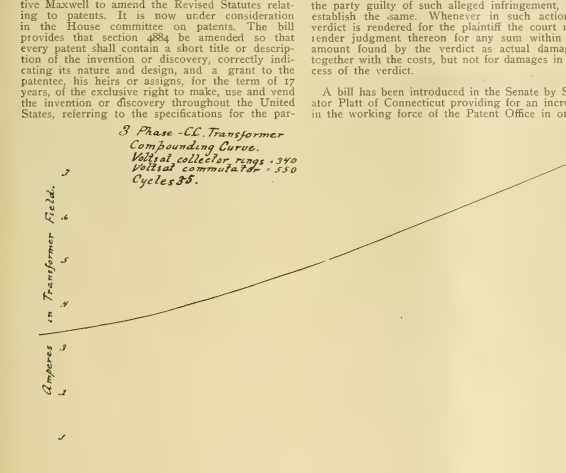

FIG 19. THREE-PHASE MACHINERY.

In connection with the International Union for the Protection of Industrial Property, which was formed in 1883 through the convention concluded at Paris on March 20th of that year, the Union for the International Registration of Trademarks is of importance. This subordinate union was formed at the conference at Madrid in 1890 and concluded by an arrangement signed at Madrid, April 14, 1891. It includes at present nine nations. The purpose of this union is to enable a citizen of one of the members of the union having registered his trademark in his own country to secure registration of that mark in all the other countries of the union without the difficulties and delays attendant upon applying separately for registration in each country.

The importance of having trademarks protected, and in many countries registration is necessary to protection, has been forcibly impressed upon American manufacturers who, on sending their goods into a foreign country, have found the very trademark which has become of value to them registered in that country to some citizen of that country who made application for registration for no other purpose than to enable him to demand of the American manufacturer a price for the right to sell goods under that trademark in that country. This has frequently happened, especially in Germany. A United States manufacturing firm, whose trademark is known from one end of the country to the other, recently complained to the Patent Office that its trademark had been copied and registered by a German manufacturer, who was able, by virtue of his registration, to stop the American manufacturer's trade in Germany. As in a number of European countries registration of a trademark is attributive of property in such mark and is granted not to the first adopter and user of the mark, but to the first applicant for registration, and as in these countries the registrant can under the laws forbid the importation of goods marked with the trademark registered by him, or even compel the seizure of such goods, it is evident that such registrant has the manufacturer who is the rightful owner of the mark completely at his mercy so far as trade in that country is concerned.

It is believed that the international registration of trademarks, which may be effected through the union, would be of material value and is practically indispensable to those of our manufacturers who desire to develop their foreign trade. In the interest of these manufacturers it is urged that the United States should become a member of this union.

At the recent conference of the International Union, which was held at Brussels, the United States delegates, Hon. Bellamy Storer, minister to Belgium, and Mr. Francis Forbes, took an active interest in the discussion of changes proposed in the agreement respecting the international registration of trademarks, though the United States was not a party to that agreement. The purpose of this agreement is to make the international bureau at Berne the center of a cheap registration which shall be efficient over the territory of the adhering states. The fee for this international registration was reduced to 100 francs for the first mark and 50 francs for each of all other marks for registration at the same time by the same owner.

Senator Hanna has introduced the following amendment to the patent laws:

"That in cases of infringements or alleged infringements by purchasers or users of any patented device whatever, any individual, company or corporation, to establish their claims upon patents of said devices, shall, in the courts having jurisdiction, enter suit against said purchaser or user within the space of five years from the date of the first alleged infringement by said purchaser or user, or be forever debarred from collecting royalty or damage for the use of said device, to the end that the purchaser shall become the owner in reality as well as in name, and not be further molested.

"That any individual, company or corporation owning or controlling patents acquired by purchase or otherwise, in case of alleged infringement by any inventor or manufacturer of any device whatever, to establish their claim of infringement on said device shall, in the courts having jurisdiction, enter suit within the space of one year from the date of said infringement, or be forever debarred from collecting damage from said inventor or manufacturer, though this act shall not be so construed as to debar any individual, company or corporation from establishing their ownership to patents upon said device thus manufactured."

The reasons offered for the presentation of this bill are that there exists at present an abuse of the rights and privileges granted to owners of patents which has become widespread and is causing great inconvenience and unnecessary expense to innocent purchasers of devices upon which two or more individuals, companies or corporations claim patent. These claims are said to be made often through the use of telegrams, circulars, pamphlets, letters and advertisements, threatening and intimidating purchasers of such devices, the intimidation sometimes extending over months and years. In a majority of cases it is contended that the cost of defense of the purchasers' rights would be far in excess of the amounts claimed, and in these cases settlements are forced to be made before claims have been thoroughly established. It is therefore contended that such a bill will give ample time to recognize the rights of inventors and yet protect purchasers from great inconvenience and loss, such as is frequently sustained under the present system.

Western Electrician.

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO.

TELEPHONE, MAIN 1746.

EASTERN OFFICE: 108 TIMES BUILDING, NEW YORK.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—the only general electrical paper published in the West—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

Diplomatic circles are in a state of excitement over the discovery that there has been considerable tampering with the English government's dispatches, relating to the negotiations over the eastern complications. When events in the far East began to assume a serious aspect, the British Foreign Office made the unpleasant discovery that its dispatches were being tampered with, and it became necessary to discard the old cipher code and devise a special one. It was concluded that the tampering occurred in China and that the wires between Pekin and Shanghai had been tapped. One incident that was particularly exasperating is related. An important dispatch addressed to the British minister at Pekin disappeared on the way, and frantic efforts are now being made to find it. The disappearance was probably accidental, but the Foreign Office is much perturbed. All employes of the Eastern Telegraph company are Englishmen, and their faithfulness is not questioned.

Municipal elections in Chicago and Milwaukee this week and in Des Moines last week indicate that greater restrictions will be placed upon quasi-public corporations hereafter, if the temper of the people was rightly shown on these occasions. The successful candidate for mayor in Des Moines is an avowed champion of municipal ownership, Milwaukee's new mayor was elected on a platform pledging him to the establishment of a municipal-lighting plant and reduction of street-railway fares, and the chief feature of the Chicago contest was the movement for the election to the council of men pledged to the exaction of compensation for the city for all public franchises. The Allen law was made an issue, and those who supported that measure with few exceptions suffered defeat. The result in all these places, particularly Chicago, is fraught with interest to quasi-public corporations. In Milwaukee there were many side issues that tended to heighten the effect, but it is unnecessary to review them here. It is sufficient to know that they combined to promote the election of the men who bitterly assailed the existing corporation, with the result that the interests represented by Henry C. Payne received their first public set-back in six years. No doubt Mayor McVicar's personal popularity and his prominence in the association of mayors helped to ensure his re-election in Des Moines.

Popular Science News prints a communication from Lewis Swift in which the writer takes issue with Dr. Gilbert and all the philosophers and scientists from that time down to the present day in explaining "Why the Magnetic Needle Points North." To begin with, the statement is made that "the earth is no more a magnet than is a piece of wood." It is contended instead that "it possesses the power called gravitational attraction, and so has a piece of wood," but it is insisted that "neither the earth nor wood has any effect upon a suspended magnet."

The explanation advanced is "that there is a constant flow of electricity around the earth parallel to its magnetic equator; and the fact that a suspended magnet will always assume a direction at right angles to such a current is the cause, not the attraction of the earth." The suggestion is offered that while "the source of the electricity is, of course, unknown," it "probably is the sun."

Nothing is said to fix the identity of the writer, but it is probable that Dr. Lewis Swift, an amateur in astronomy, who gained some distinction about 15 years ago by his successful search for comets, is responsible for the communication. Dr. Swift has dabbled in all branches of science and has evidently lost none of his old-time enthusiasm; nor has his appreciation for sensational discoveries diminished.

The New York Sun having commented on "The Doom of Snoqualmie," basing its editorial on a recent illustrated article in the Western Electrician on "Snoqualmie Falls Transmission," the Electrical Review comes to the front with the statement that it presented a "larger and better engraving of Snoqualmie Falls" over three years ago. The Review misses the point of the Sun article as well the purport of that in the Western Electrician. The Sun dwelt on the commercial utilization of a "glorious expression of Nature's visible force;" the Western Electrician supplied the information of work in progress, on which the contrast of Nature's grandeur and man's invention was based. Three years ago the Electrical Review did print a picture of Snoqualmie Falls, but it was in connection with a "Snoqualmie Falls Electric Power company" which never materialized in action and which at the time was trying to sell bonds in New York city. The promoters' scheme failed, and now the Western Electrician has given the news of a new company, with a different and enlarged plan, which has actually begun work on a very interesting plant. Pictures and descriptions of Niagara Falls were printed a hundred years ago, but the first illustrated description of the power plant now in operation there had a very different meaning to engineers. As to the Review's picture, it was but a trifle larger than that in the Western Electrician—though the size is of no importance—and it was certainly no better.

Discussion of methods of charging for telephone service continues to attract attention. It has been suggested in France that a scale of charges be established either upon the number of calls per annum or upon the total time that the subscriber is in circuit during the year. Further modification is advocated, depending upon whether a call is to a subscriber in the same or in a distant district. The working expenses of the company depend upon the number and duration of the calls, and upon the number of distinct offices through which communication has to be established for a particular call. It is explained that if the subscribers are on different exchanges the switching operations occupy time and require an increased staff. The method of charging by annual tax, supplemented by the number and duration of calls, has many advocates, but the dual system of tariff leads to complication, and choice has to be made between a tax founded upon the number of calls and one proportional to the time consumed. Preference is given to a tariff based upon the number of calls, where any system of this kind is to be employed, but thus far the telephone interests have found a flat rate far more desirable in this country. In some instances where the Bell company attempted to force a tariff schedule upon its subscribers it found considerable difficulty, and in one case particularly, that of Rochester, N. Y., it was ignominiously defeated. Since that time it has lost much of its enthusiasm for the tariff schedule.

Several dramatic incidents were reported in connection with the flood at Shawneetown, Ill., last Sunday, but none possess more interest than the heroic attempts that were made by the telephone company's employes to give the alarm and summon relief. Cypress Junction, which is five miles from the scene of the flood, was the first place to hear the news. The bulletin came by long-distance telephone. It was of dramatic and horrible brevity.

"The levee has broken! The water is rushing in from the bend a mile and a half up the river. Already 250 people are drowned in the lower part of town and——"

At this point the operator sending the message ceased speaking, the wires went down and all efforts to regain connection with Cypress Junction failed. A few particulars were received at Evansville, Ind., some time afterward. Two citizens of Shawneetown who had escaped the flood rowed a skiff to a small town near by and telephoned the brief facts of the catastrophe. They had but few details to give. An appeal for aid was received by the mayor of Evansville later in the evening. The message was transmitted by a telephone lineman, who climbed a pole four miles above Shawneetown and made a temporary connection to call for aid. Other towns in Indiana were also notified and a few details were thus gathered. The manager of the telephone exchange at Shawneetown gave Mount Vernon its first definite news of the big inundation at the little city down the Ohio River. His message contained the following statement: "I am four miles from Shawneetown now. I escaped and made my way here with a portable telephone. I climbed up a telephone post and made a connection, and that is how you are getting the news."

The telephone company's employes proved themselves to be heroes of the occasion. Their energetic and intelligent efforts ensured immediate relief for the sufferers, and demonstrated again in no unmistakable manner the importance to every community of electrical communication with the outside world. Had it not been for the telephone neighboring cities could not have been notified of the dire necessities of the people of Shawneetown and relief expeditions could not have been summoned as speedily as they were in this case.

WAR NEWS.

As this number of the Western Electrician goes to press the issue of peace or war between the United States and Spain hangs trembling in the balance, with the probability that war will ensue. The electrical men are alert and patriotic citizens and will take an honorable part in the conflict, if one shall come. Some of the electrical preparations and proposals for war are noted below.

Telegraphic Preparations.—Of course one of the most important of the electrical war precautions is that relating to telegraphic communication along the coast and to and in the West Indies. The government is working energetically in this direction. A dispatch from Savannah states that it has arranged for the establishment in one day's time of its own telegraphic system for secret service along the entire Atlantic coast. The whole coast will be divided into districts. Savannah will be district No. 4, and headquarters will be established there. The sub-stations in Savannah's district will be Cape Romain, Charleston, Hilton Head, St. Simon's, Mayport, Fla., and Cape Caneve. The government intends to build houses on the beach, where naval reserve officers will be stationed with telescopes to keep watch and report to headquarters in the city all ships sighted at sea. The system will have connection with the Western Union telegraph wires and the long-distance telephone. Three operators will be stationed in the main office in Savannah, which will be in full charge of the office and the signal corps. The Savannah office will be in direct communication with the Navy Department at Washington.

In New York, Boston and other harbors the work of connecting the coast defenses for electrical communication is proceeding with energy. As a result of representations made by Capt. James Allen, signal officer stationed at Governor's Island, to General A. W. Greely, chief signal officer, of the absolute necessity of the expenditure of more than $25,000 in the telephonic and telegraphic connections between the fortifications in New York harbor, New York will get $25,000 more to complete this work according to the original plans. Boston will get about $10,000, Philadelphia about $5,000, and Washington, Baltimore, Newport and Portland, Me., will also get increased appropriations. The total increase for the Department of the East is $96,000. This increased appropriation will make it possible to do an especially important work. All coast fortifications are provided with range finders for the purpose of determining the distance from the fortification of an enemy's vessel. These, if they are to be used effectively, must be supplemented by telegraphic apparatus, to enable the man in the tower to telegraph to the gun pits the range of the approaching vessel. The majority of the range finders in the fortifications are now so equipped. Now every one will be within 30 days.

One serious problem is the possible interruption of cable service in the West Indies in the event of war. A dispatch from Washington on Monday stated that an arrangement was reached during the day by which the United States and France will co-operate through their ministers at Denmark in the establishment of a public cable station on the Danish island of St. Thomas. The cable is owned by a French company, but its use has become of vital importance to the United States government, owing to the possible base of naval operations in the Leeward Islands. Secretary Long was particularly desirous of having this cable arrangement effected. As a result of conferences a dispatch was sent to the United States minister at Copenhagen asking him to secure the consent of the Danish government, and at the same time the French authorities arranged to have their minister at Copenhagen exert similar influences. With the Leeward Islands, of which St. Thomas is a center, as the probable center of any naval operations which may result from the present crisis, it is recognized as of vital importance to secure cable facilities not controlled by Spain. At present the cable line touching at Puerto Rico, and subject to Spanish control, is the only means of communicating with these islands. The French cable lands at St. Thomas, but the station is merely for testing purposes, and messages are not received or delivered. It is now proposed to have this station turned into a regular bureau, in which case the government could be brought into close cable communication with any naval rendezvous there.

Under date of April 5th Mr. Curtis telegraphs from Washington to the Chicago Record this statement: "As if in anticipation of trouble the Spanish government has recently laid new telegraph cables from Santiago, on the south side of the island, to Santo Domingo and to Kingston, Jamaica, which are connected both with the Windward Islands and South America and also with the Bermudas, in order that they may have communication with Spain quite independent of Key West. Until recently all of the dispatches that have passed between Havana and Madrid were sent by way of Florida and New York, and that line continues to be used to a limited extent. In case of war, of course, it would be cut off, but the authorities at Havana would still have three lines to choose from; the first by way of Jamaica and Panama, down the west coast of South America and across the continent to Buenos Ayres, up the east coast as far as Pernambuco, and then across the Atlantic to Lisbon or to Cadiz. The second route would be by way of Haiti and the Windward Islands to Trinidad, Demarara, Para and Pernambuco, and the third by way of Haiti, to Bermuda. One of the first things to be attempted by our government would be to cut all these cables, in order that the authorities at Havana might have no means of communication with the home government."

War News in Chicago by Telephone.—With customary enterprise General Manager Hibbard of the Chicago Telephone company has determined that every one of the 14,000 subscribers of the Chicago exchanges shall be informed if war is declared within 20 minutes after the official declaration is issued. Just as soon as the news is received and verified by the company every operator will begin to ring up subscribers and notify them as quickly as possible. "Our idea in doing this is to inform our patrons of the declaration probably quicker than they would otherwise get the news," said Mr. Hibbard. "We are a quasi-public corporation and we rather consider it our duty to act this way. It is a tremendously important question and everybody is keyed up to a high tension awaiting the final word in the affair. We figure that we can inform our patrons—everyone of them—within 20 minutes after we get the news. Of course we will try to guard against any canard, but in no event will we assume responsibility for the news as we send it out. Our operators will simply tell the subscribers that we have received it as news."

Cable-layers for Emergency Service.—The following statement is published by the New York Sun: "From one of General Merritt's staff officers it was learned that the Western Union and the Postal Telegraph companies have begun to organize corps of skilled electricians, whose services are to be offered to the government should war be declared. The Postal Telegraph company has already organized three companies of 50 men each in New York and an equal number in Boston for this service. The particular work expected of the men is the laying of submarine cables and connecting them with submarine mines and torpedoes. Every man in each company has been provided with a kit of tools, which, under orders, he carries with him day and night. The men have been informed of the service expected of them, and they have been informed that, should war be declared, they would draw their salaries from the company as well as their pay from the government."

X-ray Proposed for Military Surgery.—Lynde Bradley of Milwaukee has devised plans for the use of the X-ray on board of war vessels and on the field. Mr. Bradley says that while it would be a simple matter to bring the X-ray into use on a warship, considerable difficulty would be attached to the introduction of the appartus on the field. A small outfit would have to be mounted on wheels for field use. The apparatus would, however, be much lighter and more portable than may be imagined, and his field apparatus could be finished in a week. The great help that the X-ray would be to surgeons lies in the quick method of locating a bullet or splinter in a man's body, a fracture of a bone or other serious injury.

Searchlights.—The war excitement has created a demand for searchlights for naval and coast-defense use. Of course all the regular ships of the navy are supplied, but projectors are needed for the auxilliary fleet and along the coast. It is said that the government has practically closed a contract with the General Electric company for eight 400,000 (projected) candle power searchlights with dynamos, to be set up in the fortifications in New York harbor. This order will be supplemented in a short time by one for several more to be placed elsewhere. According to the present plan four will be set up near the observation tower at Coney Island, and one more will probably be set up at Fort Hancock. The greatest delay that will be experienced in furnishing the searchlights on short notice will be due to the reflectors, which cannot be ground and tested without the lapse of some time. However, it is stated that there are available for purchase about 400 mirrors in France, England and Germany, and none elsewhere, and that 20 of the best of these mirrors have already been bought.

The largest searchlight that had a place on the top of the manufactures building at the World's Fair has been brought from Sandy Hook to Fort Monroe, Va. It will illuminate Hampton Roads from shore line to shore line.

Electrical Firing of Mines.—Electrical circuits play a necessary part in the explosion of submarine mines in harbors. The following story, sent by the Associated Press from London on April 4th, is of especial interest to electrical men:

Details have been obtained by the Associated Press of the manufacture of submarine mines in London for Spain, which was first brought to the attention of the United States embassy and cabled to the Associated Press on March 5th. A man whose cards described him as being an electrical engineer and whose name was forwarded at the time to Washington, then said he sold to Spanish officers in London several years ago a large number of mines, eight or ten of which were placed in Havana harbor. He said they were made in a special way, had a specially constructed cable, which he can identify if the smallest piece is produced, and he added that some of the mines were fixed so that they could be fired from a fort, while two of them had bulbs so arranged that they would explode upon a vessel coming into contact with them. The man added, however, that he did not believe the bulbs would be used in water as shallow as that of Havana harbor. Finally, the man exhibited plans of one of these mines, which he said was most likely to produce the effect described as causing the wreck of the Maine. It was numbered "2" and was constructed to contain 500 pounds of gun cotton.

Lieutenant Commander J. C. Colwell, the United States naval attache, has since investigated the matter, and has made a report on the subject to the United States government. The facts learned strongly tend to show that Havana harbor was mined, and they unquestionably prove that Spain purchased mines for that purpose. The firm of Lattimer, Rhodes & Clark, electrical engineers, during 1887-88, filled a large order for Spain of a lot of mines, in which were used 14½ tons of gun cotton. The work was directly under the surveillance of General Fernandez and Captain Bustamento. The latter was then the head of the Spanish torpedo school. By order of these officers the mines were divided into four consignments—for Havana, Ferrol, Cadiz and Carthagena. The mines were manufactured under the direction of J. P. Gibbons after Gibbons' patents.

Gibbons, from whom a representative of the Associated Press obtains the information, and who furnished to Lieutenant Commander Colwell a written statement of the above facts, and outlined his theory of the explosion which wrecked the Maine, was then employed by the firm as superintendent of the topedo department. He also says a similar lot of torpedoes was manufactured for Spain in 1896.

The manager of the Westminster Engineering company, which is the successor of the aforementioned firm and with which Gibbons is connected, confirms the latter's statement as to the manufacture of mines for Spain. Gibbons, who is a former sergeant of engineers and a government inspector of torpedoes, believes the Maine's first explosion was caused by what is technically called a ground mine, containing 500 pounds of gun cotton, several of which were manufactured for Spain.

He has experimented with these mines largely at Portsmouth and says that once laid they retain their properties for 50 years. In addition, Gibbons asserts that it is absolutely impossible for them to explode accidentally, as the electric currents for their explosion are formed only by the manipulation of a complicated keyboard, especially devised to prevent accidents. Three keys are necessary, which are always kept in the possession of different officers, and, even if an outsider obtained possession of them, it would be impossible to manipulate the keyboard without instructions.

Gibbons further says the mines and their connecting cables are numbered, and he asserts he would be able to identify them if any part is secured.

Miscellaneous Notes.—The General Electric company, which is constructing the electrical apparatus for the battleships Kentucky and Kearsarge, is pushing the work with all possible speed. These ships will be the first to be equipped with electrical moving turrets and hoisting machines.

Frank C. Mason, superintendent of the city telegraph bureau in Brooklyn, has written to General Merritt offering his services to the government in case of war. He is an expert Morse operator.

It is stated that such has been the government's demand for insulated wires and cables in New York that the visible supply has been nearly exhausted.

Contracts for Chicago Street-lighting Plants.

Under the appropriation for electric street-lighting extension recently made available by the City Council of Chicago, contracts were awarded last week for much of the apparatus needed. An order was placed with the Western Electric company for 10 arc dynamos having each a capacity of supplying 150 lamps of 2,000 nominal candle power. The lump price for the 10 machines was $20,500. The engine contract was awarded to the Charles F. Elmes Engineering company of Chicago, which will supply two vertical cross-compound condensing engines of 600 horse power each, complete on foundations, for $12,075. This contract, as all others, was awarded to the lowest bidder, and it is also stated that the Elmes company made the best guaranty of water consumption and the best guaranty for the cost of repairs for five years. The American Electrical Works of Providence secured the wire order —100 miles of No. 6 weatherproof wire—at $70.12 a mile, while the lamps are to be supplied by Charles E. Gregory for $10 each. The lamps are to be 14-hour, single-carbon mechanisms, with single side-arm frames, and 1,100 are to be furnished. Smaller equipment will be supplied by the Central Electric and Western Electric companies.

The new lights are to be placed in the northwestern section of the city and on the West Side and South Side. One plant will be placed in the station at Rice and Lincoln streets which was built for a city arc-light plant, but afterward used for other purposes. In numerous instances the Chicago City Railway company has allowed the use of its poles on the South Side to carry the city's lighting circuits for this new service. Permission for similar favors has been refused by the North and West Side Street Railway companies. Mayor Harrison takes great interest in the plans for better street lighting, and he accompanied City Electrician Ellicott last week in several drives about the city to locate plants and areas to be supplied from them. He contracted a severe cold in doing so, but says he is going at it again until satisfied that the new lamps are located to the best possible advantage.

Pacific Cable Project.

Late advices from Honolulu announce that the Hawaiian Legislature is considering a bill authorizing the construction by the Pacific Cable company of a cable between the United States and the islands.

The Hawaiian bill gives the company exclusive cable rights for 20 years. The cable must be laid within 18 months after the passage of the act by the American Congress and extended to Japan within three years. It must be capable of transmitting 15 words a minute, and the toll rate between Honolulu and San Francisco is not to exceed 35 cents a word, and to Japan it is not to exceed [illegible] cents a word.

DEVELOPMENT OF THE TELEPHONE FIELD.

American Bell Telephone Company's Annual Report.

[Special Correspondence of the Western Electrician.]

Boston, March 29.—The half hundred persons who were present at the annual meeting of the stockholders of the American Bell Telephone company held in Chipman Hall, Tremont Temple, to-day, heard reports which must have satisfied them that the year 1897 had been a phenomenally successful one for the company. President John E. Hudson occupied the chair and Charles E. Hubbard officiated as clerk. The latter was re-elected clerk of the corporation and William R. Driver was also re-elected treasurer without a dissenting vote. Balloting for directors resulted in the election of the following-named gentlemen: Charles W. Amory, Thomas B. Bailey, Francis Blake, George L. Bradley, Alexander Cochrane, T. Jefferson Coolidge, Jr., J. Malcome Forbes, Henry S. Howe, Charles Eustis Hubbard, John E. Hudson, Charles E. Perkins, Thomas Sanders and Moses Williams. Thomas B. Bailey and J. Malcome Forbes are the new members of the board, succeeding W. H. Forbes and Gardiner G. Hubbard, deceased. President Hudson's annual report was in substance as follows:

"We omit, in this report, the list of cities and towns in which the underground system of wires has been adopted, with the comparative figures of mileage in successive years, which has formed part of several preceding reports. This system has now come into general use for the placing of conductors for exchange use in the closely built sections of the larger cities. While it has been found that lines carried in this way are exposed to disturbing causes, peculiar to this class of work, they secure immunity from the effects of destructive storms, and, on the whole, this may be regarded as the most durable kind of construction. The limitations of the use of underground lines as regards distances are quite obvious. So far, therefore, as the development of the art has gone, it is still impracticable to employ underground lines for what is known as toll or long-distance service. The underground system is now in use in 130 of the exchanges, and 282,634 miles of exchange wire, that is, nearly 50 per cent. of the total mileage in the United States is now carried by means of the underground conduits.

"The output of telephones and the increase of the number of exchange subscribers reported by the companies operating under our licenses are unprecedented in the history of our business. In fact, the gain of exchange stations recorded for the last two years equals the aggregate for the six years which preceded. Almost the entire increase for the last year is made up of stations connected by metallic circuits. Part of this growth may be attributed to the general enlargement of population and business throughout the country, the greater efficiency of the service, and the growing recognition of the telephone as a valuable agent for the transaction of business and the convenience of home life. In part, also, it is due to the efforts of the operating companies to bring the service within the reach of the numerous class of those who have need for a limited use of the system, and have not felt justified in incurring the expense for an exclusive circuit and unlimited exchange service. Improvements in the method of equipment have removed the difficulties which formerly attended the operation of party lines, and have made it possible, without confusion or material delay, to furnish service to two, three or more subscribers on the same circuit, who do not require a great number of connections. The system of measured service continues to grow in public approval. The subscriber pays for the specific number of outgoing exchange connections for which he contracts, or as many more as his needs require, and is at no expense for inward calls.

"During the year the long-distance lines have been extended to reach Omaha in the west, Minneapolis to the north, and southerly to Petersburg and Norfolk. There were in operation on the 1st of January, 1898, 8,778 miles of pole-line and cable and 116,116 miles of wire connecting 238 offices, an increase during the year of 1,433 miles of pole-line and cable, 8,706 of wire and 55 offices. In all there are 35 companies reached whose systems furnish our long line terminals. These companies report a total of 325,250 stations, of which 146,394 (45.01 per cent.) are equipped with metallic circuits, and of these 146,394 stations 22,028 are equipped with long distance cabinet sets. The new construction completed by companies with which we have contract relations amounted to $8,712,914. Of this sum $4,865,317 was expended upon exchange construction and equipment and $3,847,596 upon toll lines. In addition to the above, $1,484,331 was invested in real estate, to be used for company and exchange purposes. The entire expenditure for construction, including real estate to the close of 1897, has been $97,946,102.

"The long distance company had invested up to December 31, 1897, in construction, franchises, equipment and supplies, $13,888,751. The company shows an increase in gross earnings in 1897 over 1896 of 16.1 per cent., the amount for 1897, gross, being $1,870,203."

Operations of the company for the year ended December 31st compare as follows:

	1897.	1896.	Increase.
Gross	$5,130,844	4,327,324	803,520
Expenses	961,170	943,743	17,427
Net	4,169,674	3,383,580	786,094
Regular dividends	2,939,904	2,683,983	255,921
Extra dividends	743,044	677,250	65,794
Reserve for depreciation of insts.	47,216	22,347	28,869
Total Surplus	2,590,521	2,151,011	439,510

The balance sheet as of December 31st compares as follows:

DEBTORS.	1897.	1896.	1895
Telephones	$ 1,772,596	1,537,761	1,285,946
Real estate	1,052,695	1,046,126	1,045,926
Stocks and bonds	52,857,205	50,511,149	44,121,680

Farmers' Mutual Telephone System.

One of the largest farmers' telephone associations ever organized has been formed at Osco, Ill. It is a mutual association and consists of the representative farmers in Henry County. The system will practically connect all the farmers of the entire county with the towns of Osco, Cambridge, Andover, Orion, Morristown and Genesco.

The association contemplates putting in the very best construction and has adopted the Stromberg-Carlson apparatus throughout.

Bell Interests in New England.

[Special correspondence of the Western Electrician.]

Boston, March 30.—The New England Telephone and Telegraph company filed its certificate of condition, under the law, with the secretary of state at the state-house to-day. It is as follows: Fixed capital, $12,000,000; capital paid in, $11,414,300; assets, real estate, $25,219; cash and debts receivable, $1,423,574; manufactures, merchandise, material and stock, $333,511; patent rights, $14,620,934; miscellaneous, $30,000; liabilities, capital stock, $11,414,300; debts, $3,484,582; reserves, $501,438; reserve for depreciation, $1,032,919.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Iowa Telephone company at Davenport, Ia., is troubled by stray currents entering the telephone cables and damaging the service. It has thus far been impossible to trace the trouble, but it is supposed to come from the return wire of the street-railway system. This is believed to be unequal to carrying the current put upon it, and some of it gets into the telephone conduits.

The Minnesota Central Telephone company will build a line from Glenwood, Lowry and Sedan, Minn., to connect with the long-distance wire to Minneapolis.

A telephone system will be established in Lewistown, Mont., as soon as the frost is out of the ground.

The Iowa Telephone company is arranging to connect with Littleton and Jessup, Ia.

E. M. Hungerford of Billings, Mont., has been granted a franchise for an exchange in Miles City, Mont.

Jones & Winter of St. Paul have the contract to install the telephone system for Litchfield, Minn. Between 80 and 90 instruments have been subscribed for.

The Des Moines Southwestern Telephone company has been incorporated at Clearfield, Ia., with $20,000 capital stock.

George Pfeferkorn will establish a telephone exchange in St. Charles, Minn., at once.

The Northwestern Telephone Exchange company has absorbed the independent exchange at Jamestown, N. D., and will rebuild it. The company will also extend its wires from Valley City to Jamestown.

The Union Telephone company of Richland Center, Wis., proposes to extend its wires to Dubuque, Iowa.

E. B. Rowlee, of the Rushford Telephone company of Rushford, Minn., proposes to connect Stephen, Minn., with Roseau, if given sufficient patronage. There is also talk of forming a home company at Roseau and constructing the line.

The Western Electric Telephone company will connect its eastern and western systems by building a line between Albert Lea and Spring Valley, Minn.

The Iowa and Nebraska Telephone company of Spirit Lake, Ia., is arranging to build from Little Rock to Rock Rapids and Ellsworth, Ia., this spring. The company now owns 300 miles of toll line and four exchanges. The stock is nearly all owned in Spirit Lake.

The Perry Telephone company is arranging to establish a telephone exchange in Adel, Ia.

COMMUNICATIONS.

The Firman Patent.

To the Editor of the Western Electrician:

The attorneys for the Western Electric company (Bell manufacturers) having published a statement over their signature, which, by inference, indicates that the Firman patent covers all forms of multiple switchboards, and that this patent was upheld in their favor in a recent California suit, we desire to publicly announce that the Firman patent does not, in any manner whatsoever, affect the multiple transfer system of the switchboard of this company. We challenge a single particular in which the Firman patent claims refer to our devices.

WESTERN TELEPHONE CONSTRUCTION COMPANY.

Chicago, April 6, 1898.

Telephone Manufacturers.

To the Editor of the Western Electrician:

On March 26th the Western Electrician published an article under the signature of a gentleman who, the writer has good reason to believe, is officially connected with an independent telephone manufacturing company. However, the chance reader of the following passage in the article will think otherwise: "The business of a telephone manufacturing company is to sell apparatus. Operating companies do not need their assistance or direction in any particular whatever; as a rule, manufacturers are not more practical in exchange work than are promoters, and their advice is of little if any value," etc., etc. Does the gentleman realize that there are in this country more than thirty manufacturers of telephone appliances? And can he name a single "experienced telephone man" who would undertake to install an exchange system without depending a great deal on the information furnished by the manufacturer? I think not. H. P. CLAUSEN.

Chicago, April 4, 1898.

An appropriation of $1,500 has been asked for the construction of a telephone line from the United States lighthouse at Table Bluff, Cal., to connect with the general telephone system at Salmon Creek, Humboldt County, Cal.

How to Select a Telephone.

By H. P. Clausen.

For the inexperienced telephone-exchange manager it is a very difficult problem to select a telephone instrument best suited for his requirements. From the very beginning he has absolutely no confidence in the often conflicting statements made by rival manufacturers of telephone apparatus; therefore he relies much more on an opinion given by the user of a certain type than he does on the claims of the maker of that particular instrument. On first thought it may appear to be the best plan to first consult the user of an instrument under consideration and then consult the manufacturer; however, this is not always true, unless, perchance, the instrument required shall meet the same conditions exactly as those that are met by the instrument of which a practical trial has been made. Therefore if it become necessary to meet conditions not found in the system tested, an instrument constructed on a radically different plan may be required; in fact, the instrument required for one class of service might be almost useless if employed in connection with an instrument built to meet other conditions, though both may have been construced by the same maker, and in outward appearance differ in no respect whatever.

Suppose, however, that you have confidence in what a certain manufacturer might suggest, and that you ask him to quote a price on the telephone instrument it would be best to employ in connection with your system. The chances are that he will send you, with the price-list, a few simple questions, which you are supposed to answer. If you neglect to furnish the desired information, but send an order, you may be sure that the order will be entered for instruments such as are employed for ordinary service, and perhaps not at all suitable for your requirements. Therefore make it a rule to give the maker of an instrument all the information he wants relating to the manner and conditions under which you are going to operate the telephone. There is no better plan for getting just what you need, assuming, of course, that it is a responsible concern with which you are dealing.

Another suggestion for the "green" telephone manager is that it is far better when buying a telephone, the ins and outs of which he does not fully understand, to admit a little ignorance and let the salesman answer for possible mistakes, than to take the entire blame by exhibiting a superior knowledge of the apparatus under consideration.

When the necessity arises of purchasing a large number of telephones for exchange service the first cost generally receives the most consideration, whereas the maintenance expenditures that must develop sooner or later in a cheap grade of instruments seldom receive any attention at all. For use on the metallic-circuit system the telephone employed need not be quite as expensively constructed as the instrument that is required to give an equally efficient service on a ground-return or common-wire return (McCluer) system, for in the metallic-circuit system the telephone is not liable to many serious interferences that are met with in the common-return system. In contracting for a large number of telephones many points should be considered that may be relatively unimportant of themselves, but of considerable value in their relation to the conditions of operation and as bearing directly upon the question of first cost and operating expenses. The character and quality of the apparatus makes this unavoidable. Attention is therefore demanded for the essential features of construction. Let us examine the apparatus and consider the work it is intended to do.

The signaling apparatus of a telephone consists of the magneto-electric generator and a polarized magneto bell. The generator is employed at the telephone instrument for the purpose of enabling the user to conveniently generate an electric current sufficiently strong for the energizing of an electro magnet placed on the switchboard at the central office. The electro-magnet is arranged with an armature and the call recording shutter, and when properly adjusted requires only a very small amount of current, that is, about .01 of an ampere, or, more clearly, the current that passes through an ordinary telephone receiver connected in series with one cell of battery should throw the annunciator drop. The average line resistance of a metallic-circuit system usually is less than 300 ohms, and a magneto generator that will cause a call to be recorded over 10 times 300 ohms, that is, 3,000 ohms, would give an entirely satisfactory service. The generator, however, employed in connection with a ground-return system should be capable of sending a signaling current through a line resistance of at least 6,000 or 7,000 ohms, for the liability of poor ground connections, partial grounds on the line wires and other outside interference is great. Moreover, some manufacturers prefer to install a less sensitive annunciator drop at the central office, for the obvious purpose of preventing the recording of a call signal by every stray current that might pass over the line. The same rule, though somewhat modified, applies to the common-wire system.

The signal receiving apparatus of a telephone consists of two polarized electro-magnets, so set in relation to a movable armature that an attraction or repulsion of either pole will cause the armature to be moved to and fro. An extension of the armature is arranged for alternately striking one or the other of a pair of gongs, thus producing at the telephone the usual audible signal.

As a general rule the first care of the wary purchaser of a telephone is to receive an assurance that the instrument he desires to purchase will ring through a certain resistance, usually 10,000 ohms, but sometimes this requirement is raised to 30,000 and even 50,000 ohms resistance. To meet such extreme and only too often useless requirements, the manufacturer is compelled to make a more sensitive magneto ringer than is actually necessary for giving an efficient service. Though it may be true that it is some satisfaction to be able to ring a bell through a very large resistance, it is equally true that a talking service is far from satisfactory, if obtained at all, between the extremities of telephone circuits over 7,000 or 8,000 ohms in resistance. Normally, the magneto-ringer coils must be left in circuit with the line wires, and they are therefore always exposed to the damage that an accidental cross with highly charged wires might produce. For that reason the manager in selecting an instrument should make it a point to ascertain how much current the ringer coils will carry with safety, and not how small a fuse wire will protect the coils against burning out. The former, when known, will quickly help determine whether the fuse wire you must employ is of a sufficiently large size to warrant any certainty of action when the occasion arises.

The question has been asked by many: "What receiver is it best to employ, the single-pole or the double-pole?" Considering the first cost and the probable maintenance expense, there is little choice. The single-pole receiver costs less in the first place, but calls for more attention, whereas the double-pole receiver costs more but demands less attention when giving an every-day service.

There has been some discussion regarding the advisability of winding the receiver coils for a lower resistance for the purpose of eliminating somewhat the effects of extraneous disturbances, such as the inductive noises usually caused by high-tension currents on wires running parallel or passing over the telephone wires of a common-return exchange system. It may be said that there are in daily service double-pole receivers wound for six ohms resistance, which give very satisfactory results, where the regular 75 or 100-ohm receiver was not at all satisfactory. The telephone receiver is a very delicate instrument and requires to be well made, but it should not be made more sensitive than is really necessary for the proper reproduction of speech, for it is the voice current that is to be conveyed to the listener's ear, and not the pernicious wail of every wayward line of force.

The telephone transmitter is a very important part of the telephone, and good judgment should prevail in its selection. Outside appearances go for naught. The fact that an instrument talks well on making a general test does not indicate that it will continue to talk well. The American Bell Telephone company, with its numerous able engineers and immense corps of assistants, required over 10 years of experimenting before the present standard, "the solid back," was developed and adopted, together with its inherent faults.

Most transmitters may talk well for quite a long while, but, after some time, there is a gradual falling off in the general efficiency—the batteries require recharging more often than seems necessary, the receivers, the line wires, the switching appliances and the trouble men, are all called on to take a share of the difficulties an ailing transmitter may produce. The best plan to follow in the selection of a transmitter is to see that the containing case proper is made of solid metal. The diaphragm, if made of a metal, should be at least three inches in diameter, and if composed of a pressed-carbon disk it should not be less than two inches in diameter and well protected against accidental mechanical damage from the outside.

The office of an induction coil is to transform the variations of an electric current produced by a microphone, connected in series with the battery and the primary winding of the induction coil, into currents that have greater ability than the mere battery current would have, of forcing their way through large resistances. The primary winding of an induction coil should consist of as few turns of wire as may be consistent with the transmitter and battery employed. The secondary winding, it must be remembered, is a part of the receiving circuit, and as it offers a certain amount of resistance to the so-called voice currents, its resistance, or more properly, its apparent resistance, to the voice current should be comparatively low. Practically, in a telephone circuit the best results are obtained when the apparent resistance of the telephone receiver and the secondary winding of the induction coil employed are equal. However, it may be safely assumed that the induction coil, when employed as a part of the telephone, will cause less trouble and require less attention than any other part of the instrument.

The telephone employing a local battery should be equipped with an automatically operated switch that either connects or disconnects the battery as needed. The switch must also produce at the proper time either of two conditions in the telephone circuit, that is, normally a signaling or call receiving circuit, and a talking circuit when the instrument is required for a conversational purpose. For practical reasons a switch that is operated by removing the telephone receiver from its support is the best for an ordinary service. The purchaser that has some knowledge of mechanics will have no difficulty in selecting a good switch out of a lot of fairly good switches; however, the primary requirements may be mentioned. The telephone switch must perform exactly the same functions as any other kind of electrical switch by connecting the battery to the transmitter circuit and the secondary circuit to the line wires. The mechanical construction of a telephone switch should be such that the friction of all movable parts is reduced to a minimum. The body of the switch should be constructed so as to allow rigid fastening to the containing case, and the lever or receiver-supporting prong must be sufficiently strong for preventing any serious damage being done by every careless operator. The electrical requirements are that the contacts must always be made firm. Perhaps the least possible sliding motion is an advantage when the contacts are at all exposed to the collection of dust particles, but as the sliding motion creates a wear at the point of contact, it is doubtless better to select a hook wherein the contacts are made direct and properly protected against the accumulation of dust. It is needless to say that all contact points should consist of platinum and be fastened to the springs proper either by clamps, wedges or, what is the best plan, riveted fast directly to the springs.

Different people entertain widely differing opinions relating to the kind of wood that should be employed in building a telephone instrument. The old telephone manager, however, will not for a moment hesitate in recommending as the best a solid walnut cabinet, and with good reason, for the walnut woodwork will retain its true color always, whereas the originally bright color of the oak telephone is soon replaced by a flyspecked and a generally unclean appearance.

The writer's lack of faith in the serviceability of the lightning arresters such as are usually placed directly on the telephone will not permit him to make any special recommendations. However, the presence of a grounded plate near the line binding-posts, if mounted on a wood base, is a fire trap of the worst kind. Moreover, it does not offer the protection desired, for the lightning arresters should be mounted separately and on a non-combustible base in combinations with a fuse wire of the proper size for protecting the telephone. In many cases it is preferable to employ a fuse wire only, which, if properly constructed, offers ample protection against atmospheric discharges.

Telephone Legislation in Massachusetts.

[Special correspondence of the Western Electrician.]

Boston, April 1.—The lower branch of the state Legislature, after a heated debate, ordered to a third reading to-day a bill to place the telephone companies doing business in Massachusetts under the supervision of a Board of Gas and Electric-light Commissioners. This measure has created a great deal of discussion throughout the state and its passage was strongly opposed by the Bell Telephone people. The Boston Post stood behind the bill and used all of its influence to secure its adoption. The committee on mercantile affairs, five of the 11 members dissenting, reported the bill. It is entitled "An Act Relative to Charges and Service of Companies Engaged in Telephone Business," and contains the following provisions:

Section 1. All matters relating to the rates and service of companies engaged in the telephone business shall be under the supervision and control of the Board of Gas and Electric-light Commissioners. And said board shall have full power to recommend such change in the telephone rates and service as the public interest may require, and to inspect and examine the books, records and accounts of said companies, and to summon witnesses and send for persons and papers at such hearings as may be had before them. And said board shall have the same rights and powers in the premises as it now possesses in reference to similar complaints brought before it regarding gas and electric-light companies, except as otherwise provided in this act. And no increase in the rates of said companies shall be made without previous approval from said board.

Section 2. Upon the complaint in writing to said board by the mayor of any city or the selectmen of any town in which a telephone company is located or doing business within the limits of the commonwealth, or by twenty customers of any telephone company, in respect of the prices charged by said company for the use of telephone instruments or for messages sent by telephone, or of the quality of the service rendered by such company, the said board shall notify the company of such complaint by leaving a copy thereof at the office of the company, and shall thereupon, after such notice as the board may deem proper, give a public hearing or hearings to such petitioner or petitioners, and after said hearing or hearings may make such recommendation as the board deems just and proper concerning any reduction in the charges made by said company for the use of telephone instruments or for messages sent by telephone, or relating to any improvement that the board deems just and proper in the service rendered by said company; and said board shall recommend such further action in the premises as may seem just and proper to said board. The jurisdiction of said board hereby given shall extend to and embrace the prices charged by one telephone company to another telephone company as well as prices charged by any telephone company to any city, town or private customer.

Section 3. Every telephone corporation shall, at all times, on request, furnish to said board any information required by it concerning the condition, management and operation of its business, and particularly copies of all leases, contracts and agreements with subscribers or other telephone corporations, or otherwise, to which it is a party, and also with rates, charges and other facilities afforded to the public

Section 4. The said board shall, in its annual report to the Legislature, include reference to all proceedings that have taken place under the provisions of this act during the period covered by its said report, together with such suggestions as to the condition of affairs or the prices charged by telephone companies or the service rendered by such company as said board may deem appropriate.

The City Telephone company of New York city has been incorporated with a capital of $100,000, to operate a telegraph and telephone system in New York city and to Albany and Boston, and the intermediate places in New York, Massachusetts, Rhode Island and Connecticut; also on Long Island to Montauk Point, and to Jersey City and Philadelphia and intermediate places

Emerson Alternating-current Fan Motors.

The Emerson Electric Manufacturing company of St. Louis, Mo., is placing on the market a complete line of alternating-current fan motors both for desk use and ceiling fans. The desk fans are made in two sizes, 12 and 15-inch, and two styles of ceiling fans are made—one two-blade, making from 200 to 210 revolutions per minute, and being for 60-cycle systems; the other, a five-bladed type, making 500 to 600 revolutions per minute, being for high alternations from 125 to 133 cycles per second.

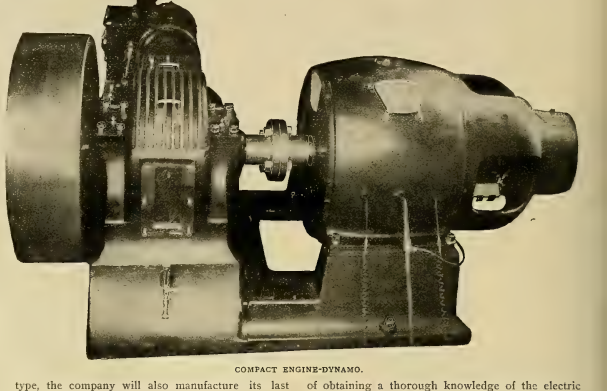
Fig. 1 shows the two-bladed ceiling fan for 60-cycle systems. This fan has a direct-acting, slow-speed induction motor without speed-reducing gear of any kind, and also without commutator or brushes. It is noiseless, the only wearing part being a single ball bearing, which is run in a cup of oil. After being placed in position this fan requires no attention for the entire season, if the oil-cup is filled at the beginning of the year. The finish of this fan is very tasteful and rich, the body of the fan being in expensive black enamel with gold decorations, hanger and trimmings being finished in highly polished and lacquered brass. This fan is regularly furnished for 12-foot ceilings without light fixture, but can be furnished promptly in nickel or oxidized copper finish with light fixtures for two, three or five lights, as ordered, and can also be furnished with hanger rods for any desired height of ceiling. The current consumption of this machine, running at the highest speed (210 revolutions per minute), is stated to be 125 watts. A second speed is also provided for by which the motor runs at 150 revolutions per minute, with a current consumption of 100 watts. This is the type machine which is regularly furnished. For special uses the company is prepared to furnish this machine with a current consumption of 150 watts on the high speed, giving a correspondingly large volume of air.

Fig. 2 gives an idea of the appearance of the five-bladed ceiling fan adapted for high-alternation systems of 125 to 133 cycles per second. In all mechanical features this fan is identical with the two-bladed fan, and only differs in the higher speed at which it runs and the different shape of the fan blades. The finish of this machine is identical with that of the C-F-38. These two types of ceiling fans are fully guaranteed by the manufacturers, who claim to have increased the amount of air set in motion by these fans from 33 1-3 to 40 per cent. over the ones manufactured by them last year.

In Fig. 3 is presented a rear view of the 1898 type of alternating-current fan motor manufactured by this company. The general appearance of the motor has been changed entirely from the former type, and the mechanical construction has been changed in a way which the manufacturers believe will be a decided improvement. The shaft of these fan motors is pressed firmly into the back cover and is made of half-inch bicycle tubing, which is case-hardened and ground accurately to size. The armature hub is composed of a larger piece of bicycle tubing into which is pressed at either end a brass bushing. This bushing is reamed out to accurately fit the hardened steel shaft. This shaft being of much larger size than has ever been used on fan motors in the past, and from the fact of its being hardened steel, will wear for an indefinite time, thus avoiding all rattle and noise. Another improvement lies in the switch plate, which is made of porcelain, the binding-post hang concealed, so that it is absolutely impossible for inexperienced persons to receive a shock in handling the motor. The 12-inch size of desk fan is carried regularly in stock for any voltage and number of alternations. The 12-inch motor is said to consume on the start from 65 to 70 watts, running at about 1,550 revolutions per minute. By turning the switch over to the position marked "on," the consumption of current is cut down to 50 watts, while the speed remains almost the same. While by moving the switch to the position marked "slow," the current consumption is cut down to about 35 watts and the speed to about 950 revolutions.

The 15-inch fan is carried regularly in stock for 7,200 and 16,000 alternations, and for 52 and 104 volts. Machines, however, can be furnished for any voltage or number of alternations. The current consumption of the 15-inch motor is 110 watts on the starting point with revolutions of about 1,550 per minute. Moving the switch over to the point marked "on" reduces the current consumption to 90 watts and the revolutions to about 1,500.

For the accommodation of such patrons as used the Emerson 1897 type of motor and prefer that type, the company will also manufacture its last year's type of motor, and is prepared to furnish either style promptly on short notice.



COMPACT ENGINE-DYNAMO.

Compact Engine-dynamo.

The Wadsworth Salt company has recently installed at its works at Wadsworth, Ohio, a neat and efficient lighting plant that is giving excellent satisfaction. The illustration shows the generating unit, composed of a 7 by 8-inch Weston Imperial engine and a 15-kilowatt, 125-volt, D type dynamo, made by the Card Electric company of Mansfield, Ohio. The armature and engine shaft are coupled together by a flange coupling, which permits of quick and easy separation, and is a desirable feature when floor space is not of great moment.

The engine and dynamo room is ample in size, nicely finished, with a handsome and convenient switchboard for manipulating the current about the works.

The engine and dynamo were first put together at Wadsworth without a hitch, and, when ready, made a run of 16 hours without a stop, hot box or trouble of any kind.

The Salt company is well pleased with its plant and already contemplates an extension.

Electrical Engineer's Correspondence School.

A new correspondence school of electrical instruction has been established by the Electrical Engineer of New York, although it will be carried on as a distinct enterprise, without reference to the policy of the journal. Herman A. Strauss, E. E., is the manager of the school, which is known as the Electrical Engineer Institute of Correspondence Instruction. The Engineer lends the weight of its influence to the new school and vouches for Mr. Strauss as a trained engineer and a practical teacher. The school is established "to enable anyone desirous of obtaining a thorough knowledge of the electric and allied arts to acquire it through the instrumentality of carefully prepared, printed lessons, supplemented by a system of confidential correspondence carried on between the student and the Institute, in which the student is at liberty to ask as many questions as he likes until he is satisfied that he thoroughly grasps every point in the lesson he is studying." Unlimited time is granted to the student to complete his course, and the terms are moderate. Each student will be a class by himself, sustaining direct personal relations with the instructor and advancing in his studies as his capability and time permit. The new Institute is not intended to be a competitor of established schools of electrical engineering, but it is desired to assist those who can only obtain a technical education by home study. The text-books deemed necessary are furnished without extra charge, and the Institute promises to deal generously with students in the matter of dropping, transferring or renewing memberships.

BOOK NOTES.

"Science Abstracts" is the name of a new English publication devoted to physics and electrical engineering that will doubtless prove valuable to students in these departments everywhere. It is well arranged, and as it is issued under the direction of the Institution of Electrical Engineers and the Physical Society of London, its standing is assured. The list of editors and abstractors contains many well-known names, and there is every probability that the new publication will prove a valuable acquisition.

Among the recent foreign publications of value may be mentioned Annuaire pour l'An 1898, publié par le Bureau des Logitudes, avec des Notices Scientifiques. Paris: Gauthier-Villars et Fils, imprimeurs-libraires du Bureau des Longitudes, Quai des Grands-Augustins, 55. This forms a yearly scientific publication, containing astronomical, geographical and statistical information, and a large number of physical tables, notably those relating to heat, acoustics, optics and electricity. It is a valuable compendium of accurate information for reference.

The American Electrical Directory, which replaces the Standard Electrical Directory, contains many changes besides that indicated in the title. For instance, it has been deemed advisable to separate the central-station directory from the street railway department. The latter has been eliminated from the present number and will be issued in a separate pamphlet, it is announced. This makes the directory purely an electric-lighting publication. In the first number under the new arrangement some interesting statistics are presented upon central-station and municipal-lighting plants.

The eleventh volume, third edition, of the electrotechnical publications from the house of Hartleben, at Leipsic, has been received. A chapter is devoted to steam, in its application to various motors. Water power and wind mills occupy the first pages, The dynamo is fully discussed and particular attention is given to regulators, circuits, systems of wiring, electric lighting and electric-lamp construction. The illustrations, which are profuse, are well executed, and embrace pretty much everything in the way of machines, lines and material, and add to the practical value of the book, making a valuable compendium for the electric-light man.

We are in receipt of a copy of Edward J. Houston's "Pocket Dictionary." This is the fourth and latest edition and is furnished in both cloth and full leather binding. This little book contains over 6,000 new electrical words, terms and phrases that have come into use since 1894. The former edition of Professor Houston's dictionary only contained 5,000 words, while the new edition contains 11,000 and about 15,000 definitions, and is the most complete and reliable electrical dictionary ever published. It is just the right size and in every way is a most admirable production. It is published by the American Technical Book company, 45 Vesey street, New York.

Berley's Universal Electrical Directory for 1898 contains the names of the members of the electrical and kindred industries throughout the world and a great deal of other valuable information.

The amount of work entailed in its compilation has considerably increased. It has been thoroughly revised, and the British alphabetical section now comprises about 9,918 distinct names, the Continental 7,872 names, the American 4,080 names and the Colonial 1,924 names, making a total of 23,974, approximately 1,136 names of individuals and firms more than were contained in the book for 1897.

For simplicity and facility of reference it is divided into four groups, namely, British, Continental, American and Colonial, which are again subdivided into alphabetical and classified sections, and in the case of the British a geographical section is given, making in all nine sub-divisions.

In addition to the new names incorporated in the present issue, much financial information, such as the telegraphic addresses and local telephone numbers, are given, and the total of pages added to the work is 70, as compared with that of 1897, making in all about 1,100 pages entirely of directory matter. It is claimed to be therefore the largest, as it is the oldest, electrical directory in the world.

In the preface the following statement will command attention:

> The one remarkable feature in electrical tramway schemes has been the introduction of American machinery, but when one remembers the extraordinary experience gained by our transatlantic friends in this branch of electrical engineering, it ought not to be surprising.

Missouri Franchise Law.

(From the St. Louis Republic.)

On motion of the attorney general the Supreme Court has advanced the suit from Kansas City to test the validity of the Julian franchise law, and arguments will be heard in the course of two weeks. In the ordinary course of business it is likely that the case will be decided some time in May.

This suit is of great importance to St. Louis, where no attention has been paid to the law, and franchises granted without any reference to its existence.

There is another case of exactly the same nature pending on appeal from the Circuit Court of St. Joseph. In this latter suit Judge Culver of the Buchanan County Circuit Court held that the law is unconstitutional, because the title does not indicate the scope of the law. The St. Joseph case, however, will be determined by the suit from Kansas City, as the latter has priority in the court.

Although many laws have been attacked of late years on account of faulty titles, the Supreme Court has not been disposed to deal with such objections in a technical sense, but has universally held that the title need not set forth the summary of the entire provisions of the law, but merely enough to indicate its nature.

In the opinion of Mr. Julian, author of the law, if the Supreme Court holds it to be valid, all the franchises granted contrary to its provisions will become utterly worthless, and in the future every franchise granted by a city will have to be first advertised for not less than 30 days in the city newspapers and then awarded to the highest responsible bidder.

Bluff City Railway.

Another link in the electric railways between Chicago and Milwaukee is about to be built by the Bluff City Electric Street Railway company of Chicago. The line will connect Highland Park and Waukegan, Ill., and will be about 17 miles long. It will have a single track, which will be laid with 65-pound steel rails. C. E. Loss, who is the president and principal stockholder of the company, has already begun the work of track construction, which will be of a substantial character.

The power house and car-barns will be built at Fort Sheridan. The plant will represent the latest ideas in electric-railway engineering, with alternating-current transmission and direct-current distribution from rotary transformers to the line. The engine, boilers and generators are now under contract for the initial installment of the plant. Three 250 horse power Cahall boilers of the Babcock & Wilcox water-tube type will supply steam, and the tandem compound engine will be of the Corliss design, built by Filer & Stowell, and rated at 400 horse power. Directly connected to the engine will be a 250-kilowatt, three-phase, 25-cycle, 5,500-volt generator, made by the General Electric company. The Arnold system will be used to connect engine and generator. A 125-kilowatt rotary transformer will be installed in the power house, and another of equal capacity in a sub-station eight miles north of Fort Sheridan.

Step-down static transformers at the power house and sub-station transform the alternating current of 5,500 volts from the generator to 380 volts. At this potential the three-phase current operates the motor side of the rotary transformer, generating direct current at 600 volts. The direct current is distributed by feeders in the usual manner to a No. 00 trolley line.

Each car will be 42 feet long with two trucks, and will be equipped with four General Electric motors of 35 horse power each. It is designed to run at a speed of 40 miles an hour, or each motor car can pull a loaded trailer at 25 miles an hour.

An interesting feature of the engineering work is the speed with which it was done. Within three weeks from the time the work was placed in the hands of Mr. B. J. Arnold, the designing engineer, the plans were perfected, specifications drawn and issued, bids received and contracts let.

Moses G. Farmer.

(From the London Electrical Review.)

It is very difficult for the mere men of the crowd to contemplate with other than wonder, or perhaps curiosity, the mental attitude of a man like Moses G. Farmer, who pursued science without a thought of the solid personal benefits to be derived from it. To day most of us, as soon as we have discovered some new fact or discerned some new bearing of an already ascertained fact, hasten to publish it, in order to obtain for ourselves priority. Indeed, in some countries, notably in France, there is an elaborate system of sealing papers, whereby a man may state in general terms something into which, perhaps, he has obtained some insight, and then, when someone else comes forward at a later date, he can produce from the archives of the Academy of Paris his hidden statement, which guarantees him that much-coveted priority. Vanity is doubtless at the root of this curious practice. This quality, for it is a quality, and a good one if it is properly balanced, is the last which we could possibly ascribe to Moses G. Farmer. In him the world had a clever, industrious worker, who observed, deduced and noted down facts, which, had they been published at the time, would have covered him with honor and renown. We can quite sympathize with this modesty, but to-day can see the pity of it, for had those notbooks been given to the world, applied electricity would, without doubt, have come more rapidly into prominence in the industries of mankind than it has done. It may be said that the new science has come on quite fast enough, but useful progress in the application and acquirement of knowledge cannot proceed too rapidly.

It would be a good thing for the rising generation of electrical engineers if a biography of Farmer could be placed in their hands. It would prove not only interesing and encouraging, but inspiring. In Farmer's work there was no cheap clap-trap, no striving after effects which would dazzle the multitude, no dashing about in order haply to light upon the fact of which he was in search, no rule-of-thumbism. He proceeded slowly and steadily, measuring his paces and calculating his distances, until he was able to gain the end he had in view.

It is sincerely to be hoped that Mr. Farmer's notebooks will be edited and published. Their contents are believed by those who have inspected them to consist of matter which was new science at that time. He was a great inventor, and deserves that certain discoveries which figure in those notebooks should be credited to him. The work of Farmer has passed unconsciously into the work of others, but had his individualism been more energetic, he would have been recognized during his life as one of the greatest leaders in the application of electricity.

Trade Catalogues in Foreign Languages.

So much has been said by American consuls and others interested in the extension of American foreign trade about the necessity of catalogues printed in the language of the country in which it is desired to do business, that a contribution on the other side of the question is of interest and importance. Such a contribution, from the manufacturer's point of view, is supplied by a letter written by Mr. E. A. Merrill, the manager of the New York office of McIntosh, Seymour & Co., to the National Association of Manufacturers. Mr. Merrill writes:

"At the same time that we wrot you we wrote a number of manufacturers with whom we are acquainted and who do a considerable export business. Their replies indicate such difference in opinion and practice in the matter that we believe it would be of advantage to the members of the association should you look into it further, not only with reference to the general question as to whether or not it pays to distribute circulars in foreign languages, but as to the further question as to how far this applies to different kinds of business.

"Take, for example, our own line of business. Our engines go to England, France, Germany, Belgium, Russia, Japan, Ceylon, South Africa, Australia, Brazil, Argentina, Venezuela, Mexico, Cuba, with occasional orders for smaller and less known countries. If we except the strictly speaking English countries, and also Japan, where the English language is spoken to so large an extent that it is unnecessary to consider any other language, there are still French, German, Russian and Spanish-speaking countries to reach, and with us the translation into any one of these languages of our catalogue is a serious matter, owing to the necessary use of technical terms and expressions which have absolutely no equivalent in those languages. Not only is the translation work a slow and expensive process, but the expense of printing is large and the expense of distribution and correspondence entailed is also large; so that any way we figure it the total expense would be a considerable burden, and thus far we have not been able to satisfy ourselves that the results would be commensurate with the cost.

"We presume there are many other manufacturers in our own and similar lines who have studied the same problem and whose attention is continually turned to it on account of the repeated statements of our consuls to the effect that other countries pursue this course and that a successful export business can only be built up by pursuing a similar policy. We would like to ascertain if it is a fact that other countries do pursue this policy in all lines, or whether as a matter of fact it may be true that this policy is pursued in the sale of what may be termed staple commodities—in other words, commodities that can be sold from samples or from catalogues. In our line of goods there is a further difference due to the fact that the number of individual orders is not large, the number of individual customers being comparatively small, but the amounts of the orders being quite considerable, so that we come in contact with comparatively large purchasers who are, as a rule, either themselves proficient in the use of the English language or whose engineers are proficient, many of them being secured from this country.

"We have gone into the matter somewhat at length, for the reason that should manufacturing concerns go into extensive advertising in foreign languages it would mean the expenditure of a great many thousands of dollars. For example, should we go into it thoroughly we should figure that it would mean an expenditure of not less than $4,000 or $5,000, an amount neither ourselves nor anybody else can afford to spend injudiciously or wastefully in export advertising.

"Another question we should like to be enlightened upon, and which has a bearing on this question, is as to the spread of the English language in foreign countries, especially as affecting trade relations. It has seemed to us that in the Spanish-American countries the use of English was making rapid strides in all branches which affect our business, and that there might ultimately be a positive advantage, although a temporary disadvantage, not to attempt carrying transactions too far."

The City Council of Dodgeville, Wis., has granted a franchise for electric lighting to W. H. Earl of Chicago.

CORRESPONDENCE.

New York Notes.

New York, April 4.—Edwin Knowles, a young man employed by the Edison company, was the victim of the first accident reported in this vicinity from the use of the chainless bicycle. He was an experienced rider, but his wheel became unmanageable at Bensonhurst, where he was riding with his father yesterday, and he was thrown to the ground, dying from a fractured skull within an hour.

At last week's meeting of the Rapid Transit Commission George L. Rives submitted the form of contract for the construction and operation of the underground railroad. The contract is extremely voluminous. Two hundred and fifty-nine sheets of drawings accompany the contract, exhibiting in great detail the work to be performed. These drawings and the specifications show a railroad of the highest grade. The contractors must undertake to run trains of two kinds—local and express trains. The local trains are to be run at an average speed, between stations, of not less than 14 miles an hour, and express trains at an average rate of speed of not less than 30 miles an hour. During the day trains are to be run to meet the reasonable requirements of the public. During two hours and a half of the night trains are to be run at intervals of not less than 10 minutes, and between the hours of 1 and and 5 a. m. they are to be run at intervals of not less than 15 minutes. The contract requires that the contractor shall supply rolling stock of a superior quality; that it shall be adequate to the requirements of the public; that schedules of the equipment shall be filed so as to make the lien of the city readily enforceable, and that the equipment shall be kept at all times in good order. It was resolved that the draft of the contract should be sent to the corporation counsel, as his approval is required by the statute.

Details of the great power house of the Metropolitan Street Railway company, on the East River, between Ninety-fifth and Ninety-sixth streets, are interesting. Contracts for Babcock & Wilcox boilers, Allis engines and General Electric generators have been let. The order for the boilers is said to be the largest single stationary boiler order ever placed, and calls for 58 of the Babcock & Wilcox wrought steel water-tube type. Each of these is to be rated at 250 horse power, with an ultimate capacity of 400 horse power. Shortly after the installation of these an order for 29 additional boilers will be placed. The engine order calls for 11 vertical cross-compound side-crank condensing engines, each direct-connected to an alternating-current generator placed between the two columns of the engine. The engines, as I gather from the Iron Age, will be of 4,000 nominal horse power each, but will have a maximum capacity of 6,600. The power house will be of brick with steel framing and trusses. It will occupy a space of about 200 by 280 feet. The building will be divided into halves, the boiler room occupying one half and the generating machinery and engines being in the other portion of the building. The two sections will be separated by a heavy wall. The side on which the boilers will be stationed will be divided into five floors. On the lower three floors the boilers will be stationed in two tiers, facing each other. The upper two stories will be formed into a steel coal-storage bin. This will extend over the entire building, and will have a capacity of about 9,000 tons. The floors will slant down toward the center, and from the lowest point in the center chutes will convey the coal to the three boiler floors. Automatic conveying machinery will take the coal from vessels at the dock in back of the building, and deliver it to any part of the bin. A smoke-stack, 350 feet high and 22 feet in diameter, will be situated in the center of this building. Large flues will connect the boilers with the stack, and in addition there will be a complete system of forced draft. The boilers will be placed in batteries of two with a five-foot passage between batteries. Ash-chutes will lead from each of the three boiler floors to the basement, whence the ashes will be conveyed by automatic machinery. The section of the building which will be occupied by the engines and generating machinery will have only one floor besides a basement and subway. The two platforms of the engines will all be connected, however, with a complete system of bridges and steps leading to them; this will give the effect of two additional floors. Each engine is to be connected to an independent air pump and condenser. These will be located in the basement of the engine room. In view of the magnitude of the plant, the piping system adopted is a most simple one. The steam pipe for each engine connects with a stand pipe in the boiler house, and this stand pipe, running in back of the boilers, connects with each. Placed as near to the engine as possible there is in each engine branch a combined separator and receiver. The exhaust pipe from each engine drops through the floor to a closed feed water heater, and then connects with the condenser. An atmospheric riser is provided for every four engines, and, when necessary, the exhaust can be [illegible] into the atmosphere. An electric crane of [illegible] span traverses the entire engine room.

Business is undoubtedly better. Inquiries are numerous, and builders of boilers, engines and electrical machinery have been doing considerable bidding during the last few weeks on the equipment of various electrical plants. The Metropolitan Electric company of Reading, Pa., has just awarded more than $60,000 worth of contracts.

Two new concerns, who will soon ask for bids, are the promoters of the proposed electric road connecting Atlantic City and Camden and the Gettysburg Transit company of Gettysburg, Pa. The former corporation is known as the New Jersey Electric Railway company and is incorporated for $3,000,000. The projectors are Atlantic City and Philadelphia capitalists. The latter company will apply for a charter on April 14th and will operate extensive electric railway lines as well as control the electric lighting of Gettysburg. It will be known as the People's Electric Light, Heat and Power company of Gettysburg. Philadelphia capitalists are at the head of the project.

Preparation for next month's electrical exhibition in Madison Square Garden is proceeding apace. The interest is widespread. Prof. R. B. Owens, director of the electrical work at the Omaha Exposition, beginning in June, has been specially instructed to visit this city in May and acquaint himself with the exhibits and the work being done. Many special features are being laid out. One is an offer of prizes for essays on the exhibition from the pupils of schools in New York and vicinity, not over 16 years of age. Another is a practical exhibit of the system of quick police communication developed by Chief McCullagh of this city. A third is a model of the Edison magnetic ore separator, built by Sigmund Bergmann, with samples of crushed ore and briquettes. A long list of judges for the telegraph tournament has been published, and it is said that the crack operators are already getting into training.

The Walker company has recently secured a handsome and commodious suite of offices on the sixteenth floor of the Commercial Cable building, at 18 and 20 Broad street. The suite includes a private hall, general offices, private offices for the officers of the company and all modern conveniences for the transaction of business. W. F. O.

Northwestern Notations.

Minneapolis, April 4.—A survey is to be made at once for the Minneapolis and Anoka suburban electric railway, and it is hoped to have the line in operation by the later summer months.

The Sac City (Ia.) Electric company has completed its canvass for stock subscriptions, and all the shares are taken. The company will be formally organized and steps taken to put in the plant.

The Electric and Water company of Little Falls, Minn., gave a reception at its power house to exhibit the improvements that have recently been completed.

A switch engine ran some freight cars off the end of a blind siding in Winona, Minn., into a tall electric-light tower, and completely wrecked it. The pole was broken in five pieces by the fall, and the guy wires snapped and some telephone wires broken. No one was hurt.

An independent electric-light plant will be installed in the Board of Trade building in Duluth, Minn.

A committee appointed by a citizens' meeting in Park River, N. D., recommends that the city erect and operate an electric-light plant.

A man claiming to be connected with the Chicago and Northwestern Railway company has been looking over the field in the vicinity of Elroy, Wis., with a view to building an electric line from Mauston, Wis., to Elroy. He says that lines will be built from Baraboo to Portage and from Baraboo to Kilbourn, to act as feeders to the Chicago and Northwestern.

A new charter is being prepared for Barnesville, Minn., to enable the town to vote bonds for electric lighting and other improvements.

Injunction proceedings have been begun at Grand Forks, N. D., to prevent the city from paying warrants for work done on the electric-light contract. The grounds on which the injunction is asked are that there is no money available for the purpose, that the city is beyond the debt limit, that no appropriation has been made for the purpose, and that the proposition has never been submitted to vote of the people.

Mr. Winslow may furnish an electric-light plant for Marble Rock, Ia.

The John Gund Brewing company's new plant at La Crosse, Wis., will be equipped with electric apparatus to operate all the machinery. The Pacific Electric company has the contract. It will include a 100 horse power generator and seven individual motors, from one to 30 horse power.

St. John's University at St. Cloud, Minn., will put in an electric-light plant of its own.

A Peoria, Ill., capitalist contemplates constructing an electric railway from the Hotel Orleans, through Spirit Lake, Ia., to Milford. He proposes to furnish electric lights and water also.

J. K. Tillotson, the promoter who is interested in electric lines at Oskosh, Wis., has received a denial from George W. Blabon of Philadelphia, that he is interested in any proposed trolley lines between Oshkosh and Berlin, Wis.

The council of Clarinda, Ia., has appointed a committee to devise some plan by which the city may become owner of an electric light plant. The city is up to the limit on bonds.

The Cudahy Packing company has awarded contracts for electric generators and motors to operate the packing plant now in course of construction at Sioux City, Ia. The contract calls for two generators, each with engine and steam supply of its own.

C. S. Weisse & Co. have been granted a franchise for an electric-light system at Sheboygan Falls, Wis.

The council of Rochester, Minn., is considering repairs to the boilers and engine of the electric-light plant, both of which are reported as defective.

J. C. Hubinger of Keokuk, Ia., is arranging to build an electric street-car line in Quincy, Ill.

There is talk of an electric-light plant for Milo, Iowa.

The Duluth Street Railway company, in answering the suit brought by the Lakeside Street Railway company at Duluth, Minn., to recover $12,416.52, which is alleged to have been unjustly charged the plaintiff, charges that the plaintiff company has refused to bear expenses which belonged to it, and they were therefore charged against its account. It names the vestibuling of cars required by law, and other items, and declares that the Lakeside company is really indebted to it to the amount of $25,496.85, for which it asks judgment.

Beside saving the city $125 per month for lighting, the municipal plant of Wadena, Minn., made a profit of $100 for the months of January and February.

Bussey, Ia., voted to grant a franchise for electric lighting to Caldwell & Co.

The electric-light company of Grundy Center, Ia., made a proposition to the council to increase the lights in the unlighted part of town rather than increase the present lights from 1,200 to 2,000 candle power.

The estimated cost of an electric-light plant for West Superior, Wis., is $75,000.

An electric-light wire came in contact with a gas fixture in a business house in Waterloo, Ia., and burned a hole through the pipe, igniting the gas. Had it not been discovered at once, a destructive fire might have resulted.

R. R. Pember proposes to build an electric railway from Sumner, Ia., to Arlington, via Maynard.

George H. Finn, who has been connected with the electrical department of the St. Paul Gas Light company, as manager, has been appointed manager of the New England Gas and Coke company of Boston, and will leave on April 15th.

Culver Bros. of Glenwood, Ia., have traded the Emerson mills for the electric-light plant. The mill property went in at $14,000 and the light plant at $15,000, Culver Bros. paying $1,000 in cash.

The gas and electric-light plant of Washington, Ia., has been declared a nuisance and residents of the neighborhood have brought suit for damages.

The Dyea Electric Light company has been incorporated at Roscoe, S. D., with $50,000 capital stock.

The Albert Lea Electric company of Albert Lea, Minn., has reduced meter rates 25 per cent., in response to a complaint from patrons. Furthermore, the meters are under the city's charge, and any patron can demand an investigation whenever he has a grievance.

The Water, Light and Power company of Watertown, S. D., has secured orders for over 1,000 lights and will put in a plant at once. For the past two years the city has been without electric light, the old plant that was put in in 1888 being worn out.

L. W. Boehner has bought the other interests in the Malvern, Ia., electric-light plant and is now sole owner. He contemplates some improvements.

The Mason City Electric company of Mason City, Ia., will move into larger quarters soon.

The city of Neola, Ia., is taking bids for furnishing an electric-light plant.

W. I. Gray & Co. of Minneapolis have made a proposition to the council of Stillwater, Minn., to furnish plans and specifications for an electric-light plant.

D. W. Hunt, formerly manager of the electric-light plant at Washington, Ia., died recently at Oskaloosa, Ia., of the grip.

A car of the Citizens' Traction company of Oshkosh, Wis., was struck by a Wisconsin Central train and the car wrecked. No one was hurt.

Truman B. Welch, superintendent of the Gas and Water company of Duluth, Minn., committed suicide by shooting himself through the head in a fit of melancholia. His affairs were all straight, his home life was happy, and there seemed to be no reason to lead him to take the step he did. He leaves a wife and two children.

An electric fire engine, using electricity instead of steam for pumping water, was tested in Des Moines, Ia., recently. The current is secured by tapping any wires that happen to be available. It was an entire success.

The Legislature of Iowa has passed a curative act legalizing the contract for a municipal electric-light plant to be put in by McCaskey & Holcomb.

Irving P. Lord and W. B. Baker of Waupaca, Wis., have been granted a franchise for an electric railway from Waupaca to the Chain o' Lakes. A similar franchise was recently granted to others, who failed to raise the necessary capital.

The Des Moines Union company will establish a powerful electric-light plant in the union depot which is being erected in Des Moines, Ia. It will furnish light for the depot and also for the yards.

The City Council of Chariton, Ia., has paid $1,000 on the judgment against the city for the electric-

light plant. The city has been behind on its funds, but the present council has been economical and is getting on a firm basis rapidly. The electric-light plant is on a paying basis, and the city debt is being steadily reduced.

William Wright of Chicago has bought the electric-light plant at Sioux Rapids, Ia., and will make a number of improvements. He will put in a new dynamo and erect a new power house at once.

The court has reopened the receivership of the National Electric Manufacturing company at Eau Claire, Wis., vacating orders of court of last December closing up the affairs. A large number of men and firms are made defendants. Some sensations are looked for in the development of the case.
C.

ELECTRIC LIGHTING.

Charles Williams, Joseph Parks and B. P. Williams have incorporated the Stuttgart (Ark.) Water and Electric Light company, with a capital stock of $10,000.

The city of Pine Bluff, Ark., has contracted with Wilber Harrison of Anderson, Ind., and N. Covington of Peru, Ind., for the erection of an electric-light plant.

During 1897 the number of central stations in France increased by 17. Direct-current plants predominate, and the dynamos are principally of French or Swiss manufacture.

Notice is given by the Lighthouse Board that on June 1st the fixed white light in the southerly tower of the Highlands of Navesink, entrance to New York harbor, will be permanently discontinued. There will be established in the tower, in place of the discontinued light, an electric light showing a white flash of about one-tenth of a second duration every five seconds. The height of the focal plane of the electric light above mean high water will be the same as that of the present light, 246 feet, and it is calculated that the light will be visible 22¼ nautical miles in clear weather, with the observer's eye 15 feet above the sea. Under certain conditions the reflection of the light in the sky will be visible at a greater distance.

ELECTRIC RAILWAYS.

It is stated that the stockholders of the Delaware (O.) Electric Railroad company have decided to offer the road to the citizens of the city for $37,500, the amount of its present indebtedness.

It is stated that the company promoting the electric street railroad at Parkersburg, Va., has arranged to issue bonds to the amount of $150,000 to construct this line. James M. Jackson of Parkersburg is one of the promoters of the enterprise.

The Chicago City Railway company has completed the construction work on the downtown trolley lines on Wabash avenue and State street, but has been prevented from putting up poles and wires on Michigan avenue, between Madison and Randolph streets, until an injunction shall have been dismissed.

Hirsch Bros. & Co. of Chicago, it is stated, recently bought the Salt Lake and Mercur railroad, a steam road opened in 1896 and running from Fairfield on the Oregon Short Line to the Mercur mining camp. The new owners of the road will change the motive power to electricity and will probably extend the road farther into the mining district.

The street railways of Marseilles will soon have 84 miles of track, and will be operated by electricity. A central station in the heart of the city will furnish current for all of the branches, and will develop at least 8,000 horse power. The fare for a ride of 5½ miles will be only two cents. Marseilles is ahead of all other French cities, not excepting Paris, in the matter of electric traction.

The South Bend and Elkhart, Ind., Electric Railway company has filed articles of incorporation, with a capital of $100,000. The incorporators are De Witt Dilworth, Arthur Kennedy and J. McM. Smith. It is proposed to build a line from Elkhart to Mishawaka, at the latter place to connect with the South Bend street railway, and at Elkhart to connect with the Goshen and Elkhart, now building.

The following paragraph is floating about, credited to the Youth's Companion. As far as the street names are concerned, it might have an actual basis of fact on an East Side line in Rochester, N. Y.: "'James,' shouted the conductor, as the trolley-car stopped at the street bearing that name. A man signaled him, the car stopped and the man alighted. A half-minute later the car neared another cross-street. 'William,' announced the conductor. Another man got out. The Irishman's eyes grew visibly larger. 'Alexander,' shouted the conductor. The third man left the car. When it had started on the Irishman arose and approached the conductor. 'Oi want to git out at Avnoo B,' he said. 'Me forrsht name is Michael.'"

Work is now progressing rapidly in effecting the change from moving cables to electrical transmission over the entire system of the Capital Traction company of Washington, D. C., and contracts have now been placed for the entire equipment of the station. The new power house will be a brick structure situated on the banks of the Chesapeake and Ohio Canal in Georgetown. It will be 298 feet deep, 62 feet wide and 65 feet high. The engine room will be about 135 by 60 feet, and will contain five horizontal tandem compound engines. They will be of the Allis Corliss type, rated at 400 horse power, and will run condensing in connection with Deane condensers. They will be direct-connected to 550-kilowatt General Electric railway generators, which will run 100 revolutions per minute at a pressure of 600 volts. The boiler room will cover about 162 by 60 feet in area. It will contain six batteries of double Cahall boilers. There will be a large coal-storage bin directly over the boilers, and the coal will be conveyed down to Roney stokers by a novel system of automatic conveying machinery. The coal will be conveyed from canal boats direct to the storage bins. A nine-foot steel chimney 150 feet high will rise from the center of the boiler room.

TELEGRAPH.

The War Department, through the Signal Office, received sealed proposals on April 7th for constructing a telegraph line from Fort Myer, Va., to Sheridan Point, Va., a distance of 16 miles. The government will furnish the wire, brackets, spikes, staples, insulators, etc., and the successful bidder must be prepared to furnish the poles and all the necessary tools and labor needed to construct a first-class line in every respect.

ELECTRICAL SECURITIES.

The action of the Louisville street-railway directors in announcing that dividends would probably be discounted on the common stock has caused disappointment among holders of those securities. The directors are charged with converting their own common-stock holdings into preferred shares before settling on the discontinuance of dividends on the common.

The General Electric company has filed the following statement of its condition January 1st with the commissioner of corporations at Boston: Assets, real estate, $659,113; cash and debts receivable, $6,560,727; manufactures, merchandise, etc., $3,896,873; patents, $8,000,000; debentures in treasury, $2,000,000; miscellaneous, $10,774,399; balance deficit, $11,308,111; total, $43,199,223; liabilities, capital stock, $34,712,000; debts and reserves, $8,487,223; total, $43,199,223.

MISCELLANEOUS.

During the quarter ended September 30, 1897, the United States exported carbons to the following destination and valuation: Vienna, Austria, $1,939.49; Bahia, Brazil, $615.18; Nuremberg, Germany, $18,705.85.

Sealed proposals are being invited until April 14th for the nnulment of an act granting the right to the ing Office at Washington, seven electric elevators. Detailed specifications and regulations with which bidders must comply may be obtained by addressing F. W. Palmer, public printer, Washington, D. C.

In Congress an amendment has been introduced for the annulment of an act granting right to the Des Moines Rapid Power company to construct and operate a power station on the Mississippi River, provided the work is not commenced within two years and completed within four years from February 24, 1898.

The people of East London, a town in South Africa, are said to be desirous that outside capital be employed to erect an electric-light and railway plant in their town. Other South African electrical projects are the erection of an electric-light plant at the Monastery diamond mine, Orange Free State, and the substitution of an electric railway for the present steam road at the Sheba gold mines.

The National Board of Fire Underwriters has issued in neat pamphlet form a "List of Electrical Fittings" which it pronounces "acceptable for use under the specifications given in the National Electrical Code." Mr. Merrill, the electrician of the board, explains that "some of the articles here classified, although not entirely reliable, are the best at present obtainable and must necessarily be used until the state of the art advances. Efforts are constantly being made to secure improvement in these and in all inferior devices."

The story is told of a man in London who conceived the idea of taking a long ride into the suburbs in an electric cab. The district to which he proposed to journey was comparatively sparsely populated, and an unlikely region in which to meet with return passengers. After the vehicle had proceeded a short distance it slowed and stopped. "The electric power," said the jehu, "has all gone." So the unsuspecting fare alighted, and, generously paying the apparently disappointed cabby his shilling, proceeded on his way. Looking back he saw the cab merrily plying for hire toward Oxford street again.

Final incorporation papers were issued on April 4th by the secretary of state at Springfield, Ill., to the American Wire company, with head offices at Chicago, and with a capital stock of $24,000,000. The subscribers to the stock are O. Owen, $4,000,000; William Thompson, $4,000,000; B. B. Ayres, $4,000,000; N. B. Harkness, $4,000,000; A. D. Waterman, $4,000,000, and P. A. Powers, $4,000,000. The directors are John W. Gates, John Lambert, Elbert H. Gary, Isaac L. Elwood, Charles Douglass, Frank B. Backes, H. S. Schuler, William Edenborn, Alfred Clifford, E. J. Buffington and S. H. Chisholm.

A special correspondent of the London Engineer says that the Japanese are diligent copyists of imported machinery. As to the quality of the machinery turned out by the Japanese, he says that if you ask a foreigner, he will tell you that they cannot make anything but rubbish; and on the strength of the strange methods they employ in dealing with their work, one may be pardoned for thinking that there might be some truth in that statement. Although probably nine-tenths of the Japanese-made machines are very worthless, the writer says that he has seen certain well-made engineering products turned out there. He thinks they are turning out better dynamos and electric motors than anything else in the engineering line. They make good boilers, and some of their engines are rather creditable. In shipbuilding they manage the plate-work extremely well, but they are no hands at riveting.

TRADE NEWS.

The American Sugar Refining company of Brooklyn, N. Y., is placing a new fireproof roof over its No. 1 boiler house. The roof will be fireproof, consisting of steel trusses covered with corrugated iron, and is being furnished by the Berlin Iron Bridge company of East Berlin, Conn.

The interesting plant of the Hartford Electric Light company, with its high-tension, alternating-current transmission from a distant water-power station, rotary transformers, low-tension, three-wire distribution and storage batteries, is the subject of an illustrated circular issued by the Electric Storage Battery company. The advantages of the battery are briefly set forth.

Notice is given that the firm of Taylor & Clark, dealers in electrical supplies at Philadelphia, has been dissolved by mutual consent. Louis P. Clark has purchased all the interest of Joseph P. Taylor in the business. All outstanding accounts will be payable to him and all debts will be assumed by him. The business will be continued at 510 Arch street, under the firm name of L. P. Clark & Co.

McCarthy Brothers & Ford have been appointed agents for the Sprague Electric company for Buffalo, N. Y. Other appointed agents are Morton, Reed & Co. for Baltimore, Md., Walker & Kepler for Philadelphia and the Pettingell-Andrews company for Boston. The Sprague automatic house elevators are being received with a great deal of favor, and many wealthy men of New York city and elsewhere are placing them in their houses. The machine in its construction embodies a number of highly ingenious features in its method of control, which is entirely automatic. By means of its devices the machine may be operated from any floor, or from the car itself.

The new edition of the catalogue of the Pelton Water Wheel company of San Francisco and New York is a mine of information for all interested in the utilization of water power, by electrical transmission or otherwise, especially where a stream of only small volume but considerable head is available. The Pelton wheel has played a conspicuous part in the development of the water powers of the West, and it is also used extensively in other parts of the United States and in foreign countries. It is said that 9,000 Pelton wheels are now in operation in all parts of the world. The catalogue describes fully the Pelton system of power and its applications. Much attention is given to the electrical transmission of power in connection with the Pelton system, and a long list of electric-power installations is published. The catalogue contains a large amount of general information of value to the engineer and includes a special notice warning prospective purchasers from infringing the Pelton patents.

The extent of the demand for electrically illuminated signs and street-advertising designs is shown by the fact that the Chase Electric Sign company has been organized in Chicago to make this type of signs exclusively. Charles A. Chase, the president, has been brought up in the sign business, being formerly connected with the B. F. Chase company, which was, a few years ago, one of the largest sign-making concerns in the city. He has also a taste for photography and electrical projection, being the inventor of the very interesting Chase electric cyclorama, described in the Western Electrician over two years ago, which has attracted considerable attention at home and abroad. Mr. Chase has made electric signs a specialty for several years, and now he is giving his entire attention to them. A. P. Peck, the manager of the company, is a practical electrician, who brings to the company the benefit

of his technical experience. The company, which has a shop at 175 Madison street and is doing a good trade, carries in stock a 16-inch letter and makes all sorts of special designs, signs and decorations. It uses a special waterproof socket, and is prepared to figure on electric-sign work of any character.

Among the foreign orders recently received by the Walker company may be mentioned 20 double No. 3-S street-car equipments, three single No. 3-S equipments and 18 double No. 3-N equipments for Paris, besides four 150-kilowatt belted generators with two generator panels. Bagnall & Hilles of Yokohama have ordered two 25-kilowatt direct-connected generators for Singapore. Recent domestic orders include two 150-kilowatt three-phase synchronous motors for the Lachine Rapids Power company, a 700-kilowatt alternator, single-phase, for the Buffalo and Niagara Falls Electric Light and Power company, two 400-kilowatt, belt-driven generators for the Syracuse Construction company, and one 120-kilowatt belted generator for the Northern Electric company of Baltimore. The Norton and Attleboro Railroad company of Attleboro, Mass., has purchased four double No. 4-A-S and two double No. 5-S equipments, besides a 250-kilowatt direct-connected railway generator. Besides the generator above referred to, the Northern Electric company of Baltimore has ordered 100 Walker arc lamps, making in all 300 in three months. The Walker company has also recently taken a contract from the government to build three disappearing gun carriages for eight-inch rifles; these carriages are to be of the Crozier type, '96 model.

BUSINESS.

The price-list of the Partridge Carbon company of Sandusky, O., gives a complete list of the prices for the many types and sizes of motor and dynamo brushes made by the company. It is valuable for reference.

Herman Andrae, vice-president of the Julius Andrae & Sons company, Milwaukee, was in Chicago last week. Mr. Andrae reports a prosperous business and states the prospects for his company were never better.

The new alternating enclosed arc lamp built by the Jandus Electric company is being called for in a way that shows appreciation by central-station managers. The lamp has a range of voltage from 100 to 120 and burns singly 100 hours on one pair of carbons. It is said to be noiseless and economical in current consumption. The Chicago office is at 753 Monadnock building. A catalogue is sent.

W. R. Garton has just completed arrangements to represent the United Electric Improvement company of Philadelphia in Chicago. This company makes all kinds of generators and motors for direct current and alternating current, as well as transformers and arc and incandescent lamps and sockets. It also manufactures a complete line of standard incandescent lamps, known as the U. E. I lamps.

The Michigan Pipe company is sending out with its compliments the catalogue of the National Cycle Manufacturing company of Bay City, Mich. Henry B. Smith, the secretary and treasurer of the Michigan Pipe company, is president of the National Cycle Manufacturing company. The motto of the latter is: "A National rider never changes his mount." The catalogue is a decidedly attractive one.

General Manager A. B. Clements of the Atlantic Alcatraz Asphalt company of New York reports that his company is having unusual calls for its product of late in the electrical line. It has recently made large shipments to many of the larger manufacturers and street-railway plants in various portions of the central and western states. It makes a grade of paint which is particularly adapted for outside structural iron work, such as the painting of trolley poles, electric-light poles, etc.

A descriptive pamphlet just issued tells all about the improved Garton lightning arresters manufactured by the Garton-Daniels Electric company of Keokuk, Iowa. The company is enjoying a fine business. Its goods are becoming more thoroughly established, are being used by manufacturers of generators and motors, and by a large number of the leading street railways and electric-light companies. The company also sells a large number of lightning arresters for protection of stationary motors, the Garton proving well suited for this purpose.

The rapid increase in the number of independent telephone exchanges has made the telephone-supply business a very important item in the business of all of the electrical supply companies. One of the items used by the telephone companies for which there has been quite a large demand is that of rubber-covered telephone cables. The Paranite telephone cables, which are being sold in the West by the Electric Appliance company, are securing, it is said, a high reputation among telephone people. The Electric Appliance company is in a position to make the most prompt delivery on these telephone cables, for the reason that it represents the only rubber-covered wire factory located in the West. The Electric Appliance company is thus enabled to ship any ordinary order for special telephone cables from the Indiana factory within a very few days after receipt, which makes an unusually prompt delivery for this class of material. The Electric Appliance company is always pleased to submit samples at any time.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued March 29, 1898.

601,233. System of Electrical Distribution. William L. Bliss, Brooklyn, N. Y. Application filed October 14, 1897.

The method of controlling the current and electromotive force of a dynamo described consists in demagnetizing the field of the dynamo as the speed and electromotive force of the dynamo increase by means of an auxiliary counter electromotive force, which increases as the speed and electromotive force of the dynamo increase and which is connected in series with the primary exciting field coil of the dynamo.

601,263. Combined Rail Joint and Bond. Herbert R. Keithley, New York, N. Y. Application filed January 3, 1898.

A single metallic piece is forged around the meeting ends of two rails, and a bonding plate interposed between the rails and joining piece.

NO. 601,233

601,268. Electric Arc Lamp. Philip F. Krug, New York, N. Y. Application filed January 7, 1897.

A stand is provided with a base having a series of sockets or recesses and with slotted sides; a supporting arm is provided with a movable fulcrum guided in the slots of the stand; carbon holders are supported from the arm, and a set screw for adjusting the arm and the fulcrum, the lower end of the set screw being adapted to engage in one of the sockets or recesses.

601,276. Electric Switch. Ocron S. Platt, Bridgeport, Conn. Application filed February 2, 1897.

A base portion is provided with circuit terminals; a movable contact bar is arranged by its movements to electrically connect and disconnect the terminals; independent spring mechanisms are provided, one normally under compression and the other relatively normally uncompressed, and means employed for compressing the uncompressed spring and releasing the compressed spring to throw the contact bar into and out of engagement with the terminals.

601,286. Fusible Cutout. Ferdinand Schwedtmann, St. Louis, Mo. Application filed May 6, 1897.

The device comprises a suitable box or casing of insulating material, line wire terminals carried thereby, a removable fuse-carrying member in box or casing, fuse terminals carried by the fuse-carrying member and adapted to be put into electrical communication with the line-wire terminals, and a removable protecting cover for the line wire terminals at the side of the casing opposite the fuse-carrying member.

601,301. Safety Device for Electric Elevators. John D. Ihlder, Yonkers, N. Y. Application filed October 15, 1896.

Provision is made for the combination with the car and motor therefor, of a potential switch arranged in the circuit of the motor, and a shunt circuit including the magnet of the potential switch and the magnet of the safety brake device.

601,318. Regulator for Organs having Electrical Air Pumps. Levi K. Fuller, Brattleboro, Vt. Application filed July 20, 1895.

A wind conductor communicates with the air chamber of an organ and with the external air, and an air pump is located in the wind conductor. An electric motor operates the air pump in combination with a regulator for regulating the volumetric capacity of the air passage between the air chamber and the mouth of the wind conductor, and means controlled by the organist for governing the regulator.

601,351. Electric Lighter for Gas Burners. Ladislas V. Lewitzki, Brussels, Belgium. Application filed April 15, 1897.

An electric circuit includes the solenoid and igniter, and means, such as indented rings and a pin on the core, for moving the valve to an open or a closed position upon movement of the solenoid core, are described.

601,357. Means for Supporting Electric Wires. Benjamin Du Bois Smock, Wickatunk, N. J. Application filed February 10, 1897.

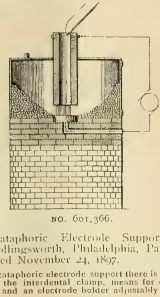
The line supports are secured to the bars and each consists of a rod provided at one end with a hook integral therewith and covered with insulating material, and the end of the hook being screw threaded and provided with a nut, the opposite end of the rod being adapted to pass through openings in the bars and being also provided with a nut.

601,366. Method of and Apparatus for Producing Calcium Carbide. Corydon L. Wilson, Charles Muma, John W. Unger, Henry Schneckloth, Amos P. Brosius and Joseph C. Kuchel, Holstein, Iowa. Application filed February 13, 1897.

The process consists in first causing the base and sides of the furnace, or the receptacle in which the process is carried on, to be lined with calcium carbide in granular form, and then causing a mixture of lime and carbon, to be fed into the space between the electrodes or the arc, so that the molten product may run into the base and sides so covered with calcium carbide.

601,367. Electric Furnace for Manufacturing Calcium Carbide. Corydon L. Wilson, Charles Muma, John W. Unger, Henry Schneckloth, Amos P. Brosius and Joseph C. Kuchel, Holstein, Iowa. Application filed February 13, 1897. Renewed February 4, 1898.

An electric furnace for producing calcium carbide is described, comprising a base, an electrode mounted in the base, a second electrode slidingly supported above the base, and having a number of longitudinal openings extended therethrough, a source of electrical supply connected with the electrode, a block of insulating material fixed to the upper electrode, and also provided with a number of longitudinal openings arranged to coincide with the openings in the electrode, so that a number of sticks of lime and carbon may be fed manually to the space between the electrodes, the upper and lower electrodes being so arranged that the sticks passed through the upper electrode will rest upon the lower electrode until melted, when they are free to run from between the electrodes, and means for raising and lowering the electrode and insulator jointly.



NO. 601,366.

601,396. Cataphoric Electrode Support. Merrill W. Hollingsworth, Philadelphia, Pa. Application filed November 24, 1897.

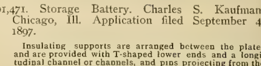
In a cataphoric electrode support there is the combination of the interdental clamp, means for operating the clamp, and an electrode holder adjustably connected to the means.

601,412. Wire Holder. Frank Canfield, Boulder, Colo. Application filed October 23, 1897.

A support for the wires of an electrical circuit may consist of the combination of a link composed of vulcanized fiber or other like non-conductor, a saddle of rubber or other like non-conducting substance having jaws for embracing the conductor, and a key or pin for clamping the conductor within the saddle.

601,454. Clamping Buckle for Electric Line Wires. Augustus H. Weikman, Palmyra, N. J. Application filed December 8, 1897.

The elastic fulcrum wire is adapted to embrace an insulator and have open projecting ends, in combination with a lever pivotally connected therewith and a clamping bail adapted to bend the line wire over the projecting ends of the fulcrum wire, and bind the line wire to the insulator.



NO. 601,492.

601,458. Electric Railbond. Frederick W. Atkinson, Chicago, Ill. Application filed October 4, 1897.

This device consists of two or more strips or wires which are bent together into two angles to approximate the form of the letter Z and terminally held together in the same plane by securing rivets.

601,471. Storage Battery. Charles S. Kaufman, Chicago, Ill. Application filed September 4, 1897.

Insulating supports are arranged between the plates and are provided with T-shaped lower ends and a longitudinal channel or channels, and pins projecting from the faces of some of the plates with their ends received into the grooves or channels in the insulating supports.

601,482. Electric Railway Signaling System. Barney Samuels, St. Joseph, Mo. Application filed May 6, 1896.

The railway signal described comprises a casing having holes or openings therein, a rod or arm rotatably mounted in the casing and having disks thereon adapted to normally cover the openings, a magnet and its armature adapted to rotate the rod or arm, an electric circuit adapted to energize the magnet, a hook arm on the rod or arm adapted to open the circuit to the magnet during the rotation of the rod or arm, and means for holding the disks away from the openings, whereby the circuit is kept open.

601,492. Automatic Cut-out. Henry F. Blackwell, Jr., Brooklyn, N. Y. Application filed August 28, 1897.

An automatic cut-out for an electric circuit is described comprising a spring-actuated arm forming a conductor, a link connected at one end to the arm and at the other end to a part insulated from the arm and a carbon point in the circuit and engaging with the link and adapted to separate the link when heated by an excessive current.

601,585. Electric Heater. James F. McElroy, Albany, N. Y. Application filed February 14, 1895.

Provision is made for the combination of supporting brackets having square openings therein, a squared spindle carried by the brackets and placed in the openings, a core of insulating material having a square perforation adapted to be placed on the spindle, a coiled resistance on the insulating material, and means for holding the same in position.

Western Electrician.

EVERY SATURDAY.

Vol. XXII. CHICAGO, APRIL 16, 1898. No. 16

A Modern Pressroom.

One of the most interesting installations of machinery in Chicago to all attracted by the nicety of mechanical applications and the ingenuity of labor-saving devices is the plant in the new pressroom of the Chicago Record and Chicago Daily News on Fifth avenue. Differing from many newspaper pressrooms, this one is clean and well lighted, and, although it is a busy place, visitors are received between the hours of three and four in the afternoon. The pictures accompanying this article show some of the interesting features of the plant, but one should see it in operation to appreciate the admirable perfection and development of the equipment. The younger readers of the Western Electrician, in particular, will find a visit to the Record pressroom instructive.

It should be understood that the Record and News, although entirely distinct in editorial control, are issued from the same mechanical plant, which is under the superintendence of Mr. Irving Stone, representing Mr. Lawson, the owner of the two properties. The newspapers have large circulations and print from 10 to 16 pages a day each, and the printing plant which Mr. Stone directs is a very large one, consuming, at the present time, 90 tons of paper and three barrels of ink a day. The new plant, which forms the subject of this article, is an addition to the older equipment and in it Mr. Stone, with the liberal backing of Mr. Lawson, has developed his ideas of what an up-to-date newspaper printing plant should be. Mr. Stone is at once a practical printer and a really gifted mechanician, and his work shows that his reputation among newspaper makers has been deservedly won.

The new plant is two-storied, occupying a basement and ground-floor store. A photographic view, taken in the latter, is reproduced in Fig. 1. The main equipment consists of two Hoe quadruple perfecting presses, numbered 9 and 10. The nearer press is shown "threaded" from the rolls of paper in the basement, as when an edition is being run off. The presses are electrically driven, and the large motor-controlling rheostats are placed in the balcony shown at the right in the general view and in greater detail in the picture (Fig. 2) on the next page. Direct current at 220 volts is obtained from the Daily News' isolated plant or from the Edison street mains. The switchboard is shown under the balcony in Fig. 2. The driving motors are located under the presses, in the basement. There are two for each press—a main driving motor and a smaller slow-speed machine to manipulate the press in "making ready." (The presses are practically duplicates of each other, and a description of one will serve for both.) The large motor is mounted on piers of masonry, and the smaller one is attached to the frame of the press. The presses themselves are installed on girder supports, resting directly on huge timbers, which take up the vibration so well that it is difficult when standing on the floor in another room to feel the presses at work. This arrangement makes a double-deck affair of the press-room. Metal grating in the floor-

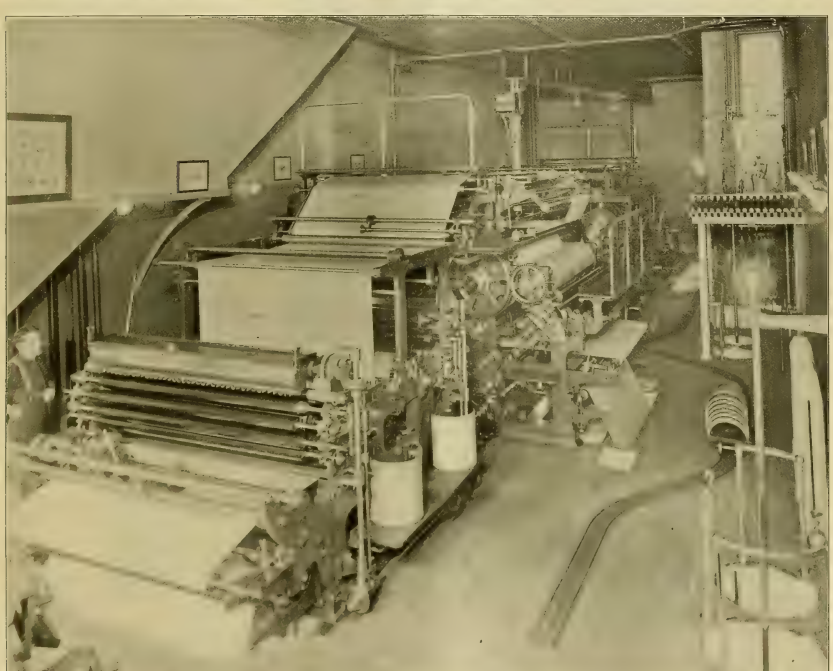


FIG. 1. A MODERN PRESSROOM—GENERAL VIEW.

ing in and about the presses add to the cleanliness of the machines, largely decrease the danger from fire and give greater circulation of air and light. The relative position and connections of the motors are shown in Figs. 3 and 4 (pages 223 and 224). The former shows the pinion side of the larger motor and the direct spur gearing, the latter the commutator side and the connection of the smaller motor, in which worm gearing is employed.

Perhaps the most important feature of the plant is Mr. Stone's electro-pneumatic system of motor control. Compressed air is used to operate the contact arms of the rheostats, and at a number of convenient points on each press air-valves and push-buttons are located. Such a point is shown in Fig. 5 (page 225). The hand shown is manipulating the handle of an air-cock which controls, through the specially constructed rheostat, the slow-speed motor which is used in "dressing the press" or making ready to run off an edition. This valve is constructed with three inlets and an exhaust, and can be set, first, to run the press slowly; second, to stop the press, or, third, to cause the air to go through a by-pass in such a manner that the press cannot be started from any other point. This last position gives a valuable element of safety, as when several men are working around the press any one of them can set an adjacent valve so that none of the others can start up the machine when it would be dangerous to do so. Below the air-valve for the small motor is shown, in Fig. 5, one of the plates from which the press operators control the large driving

motor. There is an "on" and an "off" push controlling the pneumatic apparatus on the back of the rheostat represented diagrammatically in Fig. 6 (page 225), by which the large motor is gradually started or stopped. Between these air-valves is an emergency electric push-button, by which the press can be stopped in a very few seconds. These big presses have a capacity of turning out 25,000 printed and folded 12-page papers an hour and they run at great speed. So when the paper breaks or other mishap occurs the trouble increases with extraordinary rapidity unless a very quick stop is made.

To consider now the electrical and electro-pneumatic equipment of these printing-presses in greater detail, it may be stated that the large motor is a 32-kilowatt four-pole Gibbs machine with a commutated compound winding sufficient to give an increased starting torque, which is short-circuited when the starting resistance is cut out, leaving the motor with plain shunt winding. The armature has a two-circuit series winding, and but two sets

FIG. 2. A MODERN PRESSROOM.—MOTOR SWITCHBOARD AND RHEOSTATS

of brushes are needed. The normal speed is 615 revolutions per minute. The small motor is of special design and of about four kilowatts capacity. It has six poles and a magnetic circuit of steel. Its armature has a two-circuit series winding and it has only two sets of brushes. The normal speed is about 300 revolutions per minute.

The speed of the large motor is governed by means of the rheostat by cutting out resistance in the armature circuit and increasing the voltage across the brushes, when the rheostat is short-circuited the speed is further increased by the introduction of resistance in the field circuit by means of a field regulator.

The speed of the small motor is controlled entirely by the rheostat model. The rheostat arm is operated by compressed air by means of five four-way valves (see Fig. 3) situated at different parts of the press. A small air cylinder and a similar cylinder filled with oil are placed side by side, on the face of the right-hand rheostat fronting the spectator in Fig. 2. There are, as will be seen, two of these equipments on the same rheostat, one for each press. The oil filled cylinder acts as a dash-pot to prevent any too sudden movement of the rheostat arm.

A somewhat different and more elaborate method is employed for the pneumatic control of the large motor. At the rear of the rheostat are placed three brass cylinders (see diagram, Fig. 6). The middle one contains a piston, connected by rack and pinion to the shaft carrying the rheostat arm on the face of the rheostat. It is filled with water, above and below the piston. The auxiliary cylinders are connected to it, one at the top and the other at the bottom. When the air pressure in one cylinder is released by pressing on one of the valves the pressure in the other forces the water into the middle cylinder from above, say, the reduced pressure in the other allowing the water to flow out from the bottom of the middle cylinder. Thus the piston is given a downward movement until all the water from the actuating cylinder has passed into the middle cylinder and the rheostat arm is at full-speed position. A rubber ball floats on the water in the outer cylinders and acts as a check valve by dropping into a valve-seat at the bottom of the cylinder, preventing any further pressure on the piston. In order to bring the motor to rest the air pressure on the outer cylinder now filled with water is increased above that of the outer cylinder now empty, and the water flows between the two cylinders in the opposite direction, tending to establish an equilibrium, and carries the piston with it, which turns the rheostat arm in the reverse direction, cutting in resistance and slowing the speed of the motor. The object of using water in the cylinders is to produce a uniform velocity of the rheostat arm. The auxiliary or air cylinders are connected directly with a tank which is kept at a constant pressure, and in order to reduce the pressure of one of the auxiliary cylinders a valve is opened, which allows the pressure to escape to the atmosphere, and a displacement of the water follows as above described. These exhaust pipes are carried to the "on" and "off" push-button valves on different parts of the press.

The "emergency" push-button is part of an electrical device and is in series with the field circuit of the large motor. The push-button circuit is also in shunt with an electro-magnet of such resistance that current does not flow through it unless the push-button circuit is opened by pushing a button, when part of the current is forced through the electro-magnet, energizing it and attracting an armature which releases two springs on the face of the rheostat attached to the switch opening the main circuit leading to the motor, and in so doing it also opens an exhaust valve which operates one of the auxiliary air cylinders, bringing the rheostat back to starting position. But on returning to starting position, the rheostat arm is forced against a double-seated valve, which admits air to a small cylinder placed on the lower left-hand corner of the face of the rheostat, which in turn forces up its piston, which closes the main switch again, and at the same time actuates upon a toggle which moves or kicks the rheostat arm slightly ahead to allow the double-seated valve to return to its normal position and release the pressure from the small cylinder, which operates in closing the main switch.

While this method of pneumatically controlling motor rheostats is rather complicated, it has proved efficient, very convenient and time and labor-saving. No skill is required to accelerate the motors, as the work is done automatically. The system requires two motors (and it should have been stated before that in starting the large motor the slow-speed motor is automatically cut out), but the results obtained are thought to amply compensate for the increased outlay.

The motors used are of the Gibbs type, and George Gibbs did much to assist Mr. Stone in his work. Kohler Brothers, who sold the motors, also took great interest in the plant, which may be said of every electrical man who has seen it. The Cutler-Hammer Manufacturing company built the rheostats after Mr. Stone's designs.

Of many special and novel features in this interesting plant, only a few can be mentioned here. One is the paper hoist and carrier which, rising between the presses, takes the folded papers and delivers them at the mailing table a hundred feet away perhaps. The hoist is pulled up by a wire rope, and in Fig. 1 it is shown near the top of its travel with a bunch of 150 papers in it. It is operated by an electric motor in the basement, a foot-push at the operator's command throwing in a clutch which communicates the motion of the motor to an ingenius attachment which pulls the hoist to the ceiling and lets it drop easily back. The hoist pauses at the top long enough for an automatic device to transfer the bunch of papers to a moving endless belt, driven by another motor, which carries the papers around a corner to their destination.

Another feature which is unique is the magazine reels, which are loaded with the great rolls of paper, so that 60,000 16-page papers can be run off a press without stopping the machine. Each press has two magazine reels, each reel having a capacity of four rolls of paper. From the storeroom narrow-gauge tracks run to the reels, which are placed in the basement under the press. The roll of paper is easily pushed on a little car over the track to a sliding platform which travels under the reel. Compressed air moves a plunger which "chucks" the huge roll between the centers of one arm of the reel; the reel is given a quarter-turn and another roll is put in place. This operation is repeated until the reel is loaded with a charge of four rolls. Mr. Stone is now planning to attach electric motors to these reels, so that the time and labor of turning them by hand may be saved.

As the presses extend through two stories, the superintendent set himself at work to devise means of getting about, without consuming time running up and down stairs. It was easy enough to get down by cutting a hole through the floor and sliding down a pole in it, but getting up was a different matter. Mr. Stone has met the difficulty by devising man-chutes. He is seen coming up in one in Fig. 2, while the steel sliding-pole is shown at the left. These man-hoists or elevators are automatically operated by compressed air. A pressman who wants to go to the upper story steps on the round platform of a chute, and his weight trips an air valve operating a piston, which shoots him to the floor above, and then easily returns to its original position for the next passenger. There are four sets of poles and chutes, and they make the presses fully as convenient to work upon as though they were arranged in the ordinary shape.

It is important, as the paper passes through the press, that the tension should be kept uniform. When the press gets up to speed a little brass governor automatically controls the tension. The governor has leading from it compressed-air pipes, which connect with a sensitive mechanism which operates a pressure plate. The plate presses constantly against the paper web. If the tension loosens this plate moves up and tightens the web; if the tension grows too tight the plate falls back and the tension is relieved, and at the same time electric lights in red bulbs begin glowing as a danger signal. The pressman knows that the tightness in the web is caused by a hot box in all probability on the magazine reel. He gives the screwcap of the lubricating cups a slight turn and the bearing cools off, the red lights die out, and the little governor picks up the tension again.

The Electric Light company of Avoca, Ia., contemplates buying a new dynamo.

Regulation and Protection of the Electric Motor.[1]

By Harry H. Cutler.

Electric transmission of power is fast becoming recognized as capable of almost universal application to all kinds of machinery. Scarcely a meeting of manufacturers, trade associations or engineering societies takes place where something of a favorable nature is not said about this rapidly growing and important industry. It can be truthfully stated, however, that the public is only just beginning to recognize the adaptability of the electric motor, and that an enormous demand awaits it in the near future.

The introduction of the electric motor into general use has not been as rapid as is generally supposed. Seventeen years ago the writer took for the subject of his graduation thesis "The Losses in the Transmission of Power by Means of Shafting and Belts." The results obtained were exceedingly interesting, and it might not be out of place here to mention some of them.

It was found that five-sixths of the power consumed by the engine was absorbed in the belts and shafting of the machine shop, and the very best result obtained with every machine in the shop running full—something which never occurs in practice—was an efficiency of about 30 per cent. The following deductions were then made from these results:

Attention was called to the saving which would ensue if power could be produced at each machine by means of a miniature steam engine or electrical machine, as illustrated by the low efficiency obtained in these experiments, the power to be transmitted by pipes in the form of superheated steam, or by wires conveying a current of electricity, instead of the present system of cumbersome and expensive shafts and pulleys.

It has been known then for at least seventeen years, and undoubtedly a great deal longer, that transmitting power by means of belts and shafting was expensive and uneconomical, and a remedy was pointed out at that time which is just being recognized to-day as good practice, and yet it is safe to say that nine-tenths of our mills and factories are still wasting enormous amounts of money by clinging to this antiquated practice of belt transmission. This is what is meant by the assertion that an enormous demand is in store for the electric motor.

We now see motors not only fast displacing belts and shafting, but also operating many kinds of machine tools, traveling cranes, hoists and elevators, pumps, ventilating fans, printing-presses, mining machinery, dredges, street cars, railways, vessels, air ships, implements of war, telescopes and scientific apparatus, and in fact almost every conceivable application of power.

Now there is one peculiar feature which comes up with each and every motor that is installed, namely, that a connecting link between the motor and what it is to drive must be provided which shall be adapted to the peculiar kind of work to be performed. This connecting link is the rheostat or controller, and the rapidly growing demand for these devices has given rise to what could almost be called the profession of rheostat engineering. By means of the rheostat or controller the motor is started and stopped, its direction of rotation is determined upon and the speed at which it shall rotate is varied at will.

The same motor which drives a pump would drive a fan, a printing-press or a line of shafting as well, but the proper type of rheostat to use for these various applications of power would be vastly different in each case. Generally speaking, there are but three kinds of direct-current motors, the series, shunt and compound wound, and the best suited of these three types of motors is selected to do the work. The types of rheostats for controlling these motors, however, are so numerous that only a few can be mentioned in this paper.

By far the largest number of stationary motors in use to-day are direct-current, plain shunt-wound, non-reversing and run at a constant speed. These motors are usually provided with motor-starting rheostats, whose resistance is in circuit only during the few seconds consumed in starting the motor. Simple as these rheostats are, great care should be taken in selecting the size and style best suited for the work.

A motor that is started and stopped but two or three times a day can be satisfactorily handled with a starting rheostat that would frequently be almost useless for starting and stopping a motor two or three times a minute. A rheostat arranged to start a motor under full load to the best advantage will not start a motor equally as well at 100 per cent. overload. A rheostat satisfactory to the fire underwriters of Chicago is not necessarily adaptable to the New York authorities, and would be looked upon as unnecessary extravagance by the country trade. It is important, then even in the very simplest cases, that the character of the work should influence the selection of the proper starter or rheostat, and when it comes to applying a motor to almost any other use than that of driving belts and shafting, the question becomes of still greater importance. Most stationary motors are operated at constant speed by consumers of power, and finding out that the speed of a motor can easily be regulated at will, and are calling for appliances which will accomplish this.

I can almost say that there is but one way by which the speed of a motor, of direct current, can be changed, and that is by changing the voltage across some of its parts or windings. There are a great many ways to accomplish this. The simplest, but unfortunately the most unsatisfactory way of reducing the speed of the motor, is to reduce the voltage across the armature by inserting external resistance in series with it. This method is uneconomical on account of the current absorbed by the rheostat, and also destroys the self-regulating property of the motor. The speed of a shunt-wound motor varies approximately with the voltage across the armature or brushes; with external resistance in series with the armature, the speed will vary to a much greater extent for the following reasons: When the load on the motor is increased the current C must increase. This increase of current can only occur by a decrease in speed which lowers the counter electromotive force of the armature, thereby permitting more current to flow. But the current, of course, has also increased in the rheostat, while the resistance R of the rheostat has, unlike the armature resistance, remained the same; hence since $C = \frac{E}{R}$ we see that the electromotive force E across the rheostat must be increased in some way, in order to allow more current to flow. This increase can be derived only by slowing down the armature and reducing its counter electromotive force. A very slight increase in the load when external resistance is in series with the armature will then often actually stop the motor entirely. Such cases as this have been so frequently causes of complaint from customers, that it would appear that the effect of external resistance in series with the armature is not at all well understood by either users, owners or salesmen of electric motors in general. The prevailing opinion seems to be that a speed regulator of the type mentioned can be set so that the motor will run at a certain speed, independent of the load. In proof of this assertion, many orders can be shown from some of the largest manufacturers of motors in the country, calling for a certain number of steps in the regulator to give a corresponding number of fixed speeds for the motor.

One method of changing the voltage across the armature is to operate the motor on a three-wire system, connecting the armature across the outside wires for high speed and between the neutral and one of the outside wires for low speed. This method wastes no current and causes the motor to assume a definite speed independent of the load.

Another method, which is ideal so far as the motor regulation is concerned, is to connect the armature across a variable number of storage batteries, thus obtaining any desirable speed over wide ranges. Still another method consists in so winding the armature that the coils may be changed form parallel to series, which can be accomplished in several ways.

Altering the voltage across the field of a motor also affects its speed, but in exactly the opposite way from that caused by changing the voltage across the armature. To increase the speed of a motor we can decrease the strength of its field, and there are many ways of doing this. The simplest and one of the best is the insertion of external resistance into the shunt-field circuit. This method is not only very simple and inexpensive, but, unlike the armature regulation through resistance, it wastes comparatively nothing in heat and allows the motor to assume the desired speed and maintain that speed independent of the load.

Motors are to be had of nearly all of the large builders which will operate satisfactorily with a field variation of 50 per cent. in actual ampere-turns. The same result is frequently obtained by using a compound-wound motor, winding the series fields in separate sections and cutting out these sections one by one by means of a special switch. At least one manufacturer goes so far as to use so many of these field sections that their resistance is sufficient to prevent more than the proper amount of current from flowing on closing the circuit without using any external resistance whatever. The series windings are then cut out one by one as the armature revolves. A very powerful starting torque and a

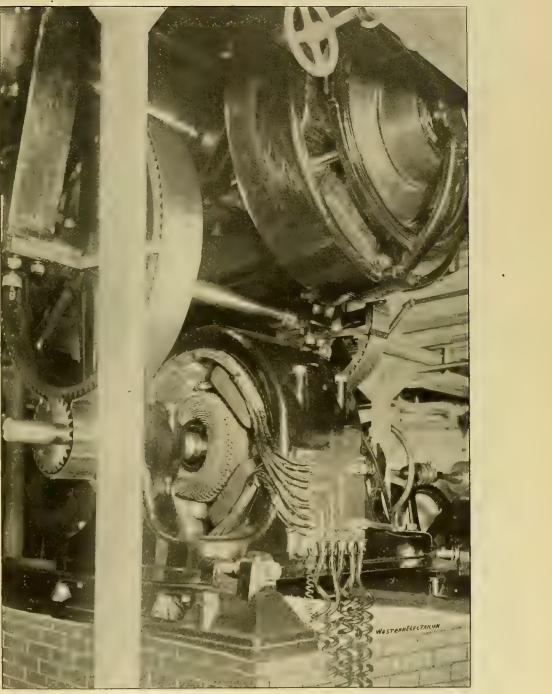

FIG. 3. A MODERN PRESSROOM.—MOTORS DRIVING PERFECTING PRESS.

1. Read before the Chicago Electrical Association, April 1, 1898.

wide range of speed is thus obtained. This method, however, will not regulate the speed independent of the load, as the field strength cannot be kept constant. It is applicable, therefore, chiefly to cases where an attendant is constantly on hand, as in the case of elevators, cranes and hoists.

One more method of varying the field strength consists in throwing the windings of the field cores into series connection for high speed and series multiple for slow speed.

Motors are sometimes regulated by means of using a separate generator for each motor, and varying the voltage of the generator by means of its field rheostat. This method is known as the Leonard system and gives perfect regulation over a wide range.

We have now before us a long list of methods from which to choose the system of regulation best adapted for the work at hand. One of the simplest and best is that frequently used for regulating motors driving fans and blowers, by means of so-called compound speed regulators. No large office or school building is now considered up to date which is not provided with artificial ventilation which can be regulated at will.

The motors which drive the fans are so belted or geared to the fan that when the fan is operating at the average speed desired no external resistance of any kind is in circuit. To reduce the speed the rheostat lever is moved to the left and resistance is cut into the armature circuit, and to increase the speed the lever is moved to the right and external resistance cut into the shunt-field circuit.

To select the proper sized motor and to determine upon the proper speed to run the fan requires an accurate knowledge of and experience with fans, air ducts and the laws of moving air. This is another subject which has not been reduced to a science by fan builders. Some builders always use a series-wound motor for driving fans and others have adopted the shunt-wound motor. When it is not necessary to vary the speed of a fan the series motor is probably preferable as being simpler, but for driving large fans, where speed regulation is always desirable, the use of a plain shunt-wound motor and a compound-wound regulator appears to be the best practice.

In proportioning the resistance for a fan-regulating rheostat it must be borne in mind that the power required varies directly as the third power of the speed, and not directly as the speed, as in driving shafting and machine tools. A regulating rheostat for a fan is therefore designed on entirely different lines, even the contacts and mechanism are different, because a fan is never started and stopped at frequent intervals during the day, and a cheap button front will do the work satisfactorily.

Diametrically opposed to the fan regulator is the electric elevator controller. This work calls for continually starting and stopping several times a minute all day long; heavy renewable contacts are absolutely necessary, as well as a special type of motor, and problems of entirely different character are to be met with. It is not practicable to build an elevator controller all ready to fasten to the wall with a string hitched to it for the operator to pull. Such devices are on the market in abundance, but should be regarded as a source of great danger.

An elevator controller, to be safe, should be embodied into and form a distinct part of the elevator mechanism, and should be attached to the elevator mechanism by the elevator manufacturer and not by the motor manufacturers or their selling agents.

There are a great many good methods of operating electrical elevators on the market. Among these methods in most common use is the system which uses a compound-wound motor and compound regulation. The motor is started through external resistance, which can consist of a rheostat or the windings of the series coils themselves. This resistance is then cut out in several steps under control of some kind of a governor; the series field coils are then cut out and finally the shunt field is weakened by the insertion of external resistance. The operation of electric elevators brings up the problem of how to reverse an electric motor. To accomplish this it is only necessary to change the relative direction of the current in either field or armature circuits. The moment we do this, however, new troubles arise; means must be provided to prevent the possibility of reversing the direction of the current without either first stopping the motor or at least inserting external resistance into the armature circuit. Means must also be provided to prevent excessive sparking or burning at the switches, as well as undue strain on the insulation of the motor.

In order to reverse a motor the field and armature have to be controlled by independent circuits. Whenever a circuit is suddenly opened that contains coils of wire wrapped around a mass of iron, a secondary or induced current is formed, which has a potential many times higher than that of the primary current. This current not only burns the switches, but is sure to injure the insulation of the motor sooner or later, unless means are taken to prevent it. Many designs of elevator controllers and rheostats on the market try to overcome sparking by opening the circuit with a snap switch, but electricity cannot be fooled in any such a simple mechanical manner as this. The flash and consequent strain on the insulation of the motor is only increased the more, and all that is gained is that the switch does not burn up quickly. This is no dream, but it is an actual fact that the market is flooded with rat-trap devices, which claim to eliminate sparking by means of snap switches. A snap switch is well enough for use in a lighting circuit, but when used in connection with a reversible motor it is a constant menace to the safety of its insulation. Everyone knows who has handled a motor that if the double-pole knife switch is pulled, even when the motor is heavily loaded, a destructive spark is never obtained. The reason for this is that the armature and shunt fields are not separated and consequently no induced current is formed in either and no strain whatever on the insulation occurs. The motor becomes a generator, energizing its own field, and gradually slows down and loses its magnetism. A similar condition of affairs can be obtained on a reversible motor. Before opening either the field or armature circuits both sides of the line should be opened simultaneously, which, of course, will cause no sparking, as just pointed out. External resistance should then be inserted into the armature circuit, and finally the armature connections should be reversed, leaving the shunt-field circuit at all times closed upon the armature. No destructive sparking or strain upon the insulation of the motor will then occur; the supply of current is absolutely cut off from the motor, and the short-circuiting of the armature through the resistance of the rheostat, occurring while the field is at full strength, acts as a dynamic brake and assists to stop the motor. This method of braking a motor is easily worked out, so that the ordinary mechanical brake never sets until the motor has stopped, or nearly so.

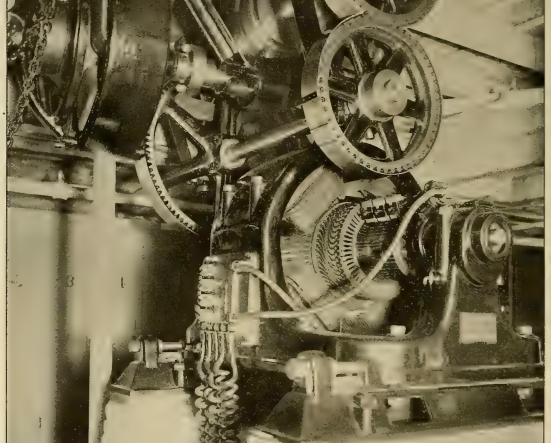

FIG. 4. A MODERN PRESSROOM.—MOTORS DRIVING PERFECTING PRESS (VIEW FROM COMMUTATOR SIDE OF LARGE MOTOR).

When an elevator is coming down with a heavy load the motor has no work to do and consequently has a tendency to run away, being driven by the weight of the elevator. If the motor is plain shunt wound and its field kept at constant strength, the load on the elevator will tend to drive the motor so much above its normal speed that it becomes a generator and returns current to the line. The speed of the motor will then increase until a potential is reached sufficiently above that of the line to consume the power derived from the effective weight of the elevator. The motor will continue to revolve at this speed, which in case of the plain shunt-wound motor would not be a dangerous speed. But plain shunt motors are now seldom used for elevators; almost all builders of elevators use compound-wound motors, or at least shunt motors whose field is weakened after starting.

Motors which bring an elevator to full speed by weakening the field would run much faster when driven by a heavy load on the elevator, and it becomes necessary for the attendant to check the speed by moving the lever back and thus strengthening the field. Should the attendant move the lever so far back that external resistance is inserted into the armature circuit, the speed of the elevator would be increased instead of decreased, as at first might be supposed, and a dangerous speed would result. This curious condition of affairs is due to the fact that with external resistance in the circuit with the armature when the motor is running as a generator, it will have to run enough faster to produce sufficient potential at the brushes to overcome the external resistance and deliver to the line the increased potential necessary to check the speed of the motor.

The application of the electric motor to the printing-press is another problem full of interesting points, which time will not permit of taking up, and we will pass on to the second part of the subject, the protection of a motor.

Motors burn out when overloaded, because they get hot. They frequently burn out also because currents of high potential are allowed to occur, which puncture their insulation. Excessive currents scar the commutators, and foreign material produces circuits which lead to damage.

To properly protect a motor from damage by the electric current, these four effects must certainly be guarded against.

Motors can only become dangerously hot by abnormal currents being allowed to flow for an appreciable length of time. A current of double or treble that of the continuous safe-carrying capacity of the motor will not do the slightest harm, unless allowed to flow long enough to overheat the motor. When such abnormal currents last only a few seconds it is neither necessary nor desirable for the protecting device to operate, and a properly designed protector should not operate unless the temporary abnormal currents exceed this amount, or last long enough to overheat the motor. Since it is the heating effect of the current which causes an overloaded motor to burn out, the most natural protection would be a device that operates through the influence of this same heating effect of the current. The well-known fuse was therefore recommended for this work and the electrical trade accepted it without question. As motors came into more general use it began slowly to dawn upon electrical engineers that they were being misled in their implicit faith in the fusible cut-outs offered by the trade. Too many motors supposed to be pro-

tected by fuses burn out, and experiments show that the ordinary commercial fuse will blow at almost any amount of current or not at all, just as it happens to feel at the time.

The manufacturers then attempted to more thoroughly standardize their fuses, and even made a faint attempt to standardize the cut-outs for holding them.

College professors took up the subject and made careful tests and wrote able articles about standardizing fuses. The conclusion which came was that the chief trouble lay in the fact that the fuses in common use were so short that the terminals and blocks to which they were fastened caused their blowing point to vary, by conducting off heat which would otherwise have caused the fuse to blow. This they said could be entirely overcome by using fuses six or eight inches long, and then we would have reliable fuses. Not enough significance appears to have been given to the cooling effect of the ever-varying drafts of air to which the ordinary commercial fuse is exposed, and therefore to expect any exposed fuse, no matter how long, to blow at a certain predetermined amount of current appears to the writer to be little short of an absurdity. People naturally became disgusted and looked around for something better with which to protect their motors. Into this breach the magnetic circuit breaker bobbed up serenely with its claim for perfection.

The magnetic circuit breaker recognizes nothing but amperes, and takes no account of whether the motor is hot or cold. Now amperes do not of themselves burn out our motors; it is the heating effect of these amperes, caused entirely by the length of time which they are allowed to flow. Volts, on the contrary, care nothing about time, so to speak; when the voltage gets high enough the current jumps, and the damage is done instantly, not through ordinary heat, but by the irresistible heat of the electric arc, which volatilizes the wires themselves. It should be noticed, howver, that excessive abnormal currents cause instant damage to the commutator of a motor, if not to the armature itself, and should be cut down as quickly as possible. This latter office the ordinary commercial circuit breaker will generally perform satisfactorily. It becomes a nuisance, however, by opening the circuit and interrupting the service at every little temporary abnormal fluctuation of current, which current would not do the slightest harm and calls for no protection. What is needed then for properly protecting a motor is, first, a device that will not allow extremely abnormal currents to flow into the motor at all; second, one that will alow slightly abnormal currents to flow through the motor, until the motor begins to approach a dangerous temperature, and, third, the device should check an excessive flow of current so that no undue strain will be put upon the insulation of the motor. No such ideal protection exists today, to my knowledge.

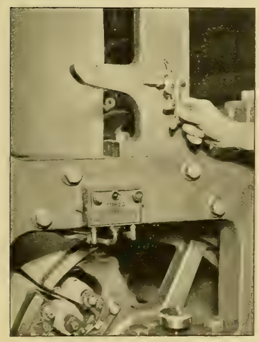

FIG. 5. A MODERN PRESSROOM.—CONTROLLING VALVES ON FRAME OF PERFECTING PRESS FOR LARGE AND SMALL DRIVING MOTORS.

The first requirement would be very difficult to meet, and the best that has been done so far is to stop the excessive flow of cuirent through the motor as quickly as possible. The other two requirements are more easily complied with. To protect a motor from heat it is evident that the heating effect of the current should be utilized in the protective device. This is accomplished in at least two devices, now on the market, namely, the inclosed fuse and a peculiar make of circuit breaker designed by the writer. [Both of these devices were shown by samples on the table.] The inclosed fuse is of the D. & W. make, and the fiber case has been removed in order to show its construction more clearly. The distinguishing feature of this fuse is the inclosed air chamber around the fuse proper, consisting of a gelatine capsule similar to those used by apothecaries for filling with quinine and other medicines.

The fuse proper is very short and is contained entirely within the capsule; copper wire leads are connected to the fuse and lead out to the terminal caps through closely-packed sand or plaster-of-paris. The capsule provides a definite amount of air within which the explosion takes place, thus greatly increasing the accuracy of blowing at predetermined currents. The force of the explosion is taken up by the layers of sand on each end, and as there is no air and but little metal to feed the arc, it immediately goes out. These fuses are surprisingly accurate, and being absolutely sparkless would certainly appear to be an ideal protection both for the motor and as against fire. They are ahead of the times, however, and the vast majority of those who operate motors still cling to the old bare fuse, working in the open air, for the protection of their motors.

Circuit breakers are being introduced very rapidly, however, as a protection for motors, and I have one here which is constructed on a somewhat different principle from anything on the market.

The action of this circuit breaker depends upon the combined magnetic and heating effect of the current. Its mechanical construction is very similar to the usual type, the chief difference being that the magnet or solenoid used to release the trip or catch carries only a portion of the current passing through the breaker. The rest of the current is shunted around the active coil of the circuit breaker, just as Edward Weston does in his well-known station ammeters. The shunt used in this circuit breaker, however, is composed of material whose resistance increases very rapidly as it becomes heated. The action of this circuit breaker is very simple. On starting up a motor under load, both motor and circuit breaker are cold; the resistance therefore of the shunt on the circuit breaker is at its lowest point and it carries then the largest part of the current flowing through the breaker; as this current continues to flow the shunt heats up, its resistance increases and more current passes through the magnet or active coil, which will finally act, should the abnormal current last long enough to become dangerous. It is also evident that an extremely abnormal current or a short-circuit would not wait for the heating effect of the current, but would cause the breaker to open instantly.

In practice these breakers are generally so proportioned as to allow a current of 50 per cent. greater to flow for a second, then would finally open the circuit, if allowed to flow for a minute or two. Any current over 60 per cent. greater than the continuous current which would finally open the circuit breaker will do so instantly.

A modification of the circuit breaker is the so-called overload attachment to motor-starting boxes, provided with the magnetic release. They are frequently spoken of as an under and overload motor starter. All the various makes of this type of motor starter use an electro-magnet for retaining a switch or rheostat lever in closed-circuit position. This retaining magnet is wound so as to connect in series with the shunt field, in series with the armature, across the lines or in series with external resistance across the lines. The overload magnet is invariably connected in series with the armature and carries usually the entire current supplied by the motor. When the current becomes excessive it attracts its armature and demagnetizes the retaining magnet by short-circuiting or opening the circuit of the windings of the retaining magnet. There are also several other ways of demagnetizing the retaining magnet.

A surprising degree of accuracy and reliability can be obtained in this way of protecting a motor from overloads. The system has, however, one chronic fault, which appears to have been entirely overlooked, and that is that no device constructed on the principle employed can possibly act quickly enough to protect a motor against extremely abnormal currents, short-circuits or lightning, notwithstanding all circulars and advertisements to the contrary. It takes time to demagnetize a magnet, no matter whether it is short-circuited or open-circuited, and this time is fatal on short-circuits and the motor will not be protected. We must then choose some combination of the various methods just described of protecting a motor. We have here on the table such a combination, which would appear to afford adequate protection for the least money. This device utilizes enclosed non-arcing fuses, the magnetic release, overload magnet and double-pole knife switch. The magnetic release affords ample protection from liability to damage from interrupted current. The overload magnet takes care of all ordinary overloads, and also performs the office of an ammeter which will indicate the approximate load on the motor at any time. The fuses are selected so as to blow on 100 per cent. overloads up to short-circuits. The overload magnet can also be provided with the time limit device, described above in connection with circuit breakers. This method of protecting a motor is laid before you for your consideration, and I desire to place myself on record as believing that with such a device on the market for protecting a stationary motor, there are very few places or conditions where the ordinary magnetic circuit breaker will afford equal protection and satisfaction, or be provided at as small a first cost.

Patent Office Improvements.

[Special correspondence of the Western Electrician.]

Washington, April 12.—Inventors will be interested to learn that the Platt bill, for revising and perfecting the classification of letters patent and printed publications in the Patent Office, has been reported favorably from the Senate committee on patents and that in all probability it will speedily become a law.

The patent system of the United States is based upon the theory that when an application for a patent is made it is to be determined whether the invention is new and useful and has been made by the applicant. This involves the examination of every application for a patent and search in the whole field of domestic and foreign patents already granted, and in all published technical works to discover whether the invention has been anticipated; in other words, whether, in the language of the constitution, it is "new and useful." The wonderful increase of inventions, at home and abroad, has greatly enlarged the field of search, and yet, if a patent is to be of real value to the inventor, and prima facie evidence of title to his invention, the search and examination must be thorough and complete. In order that this may be so it is absolutely necessary that the Patent Office shall contain all the documents and papers necessary for a complete investigation and that they shall be so classified that the examiners may in the shortest practicable time find everything relating to the subject-matter contained in the application for the patent. The better

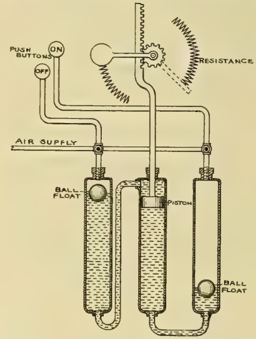

FIG. 6. A MODERN PRESSROOM.—DIAGRAM OF PNEUMATIC ATTACHMENT ON RHEOSTAT FOR LARGE DRIVING MOTOR.

the classification the more promptly the work can be accomplished, and the more certainty that a patent will not be granted for something old or known in the arts.

The increase in the field of search will be better appreciated when it is understood that each year since 1883 more than 20,000 patents have been issued by the United States. Last year the number was 23,794. The number of foreign patents issued each year is something over 60,000. The number of American patents, including designs, not including reissues or the registration of trademarks, labels and prints, issued up to January 1, 1898, exceeds 600,000. The number of foreign patents is over 1,122,000.

The pressing need now is for a more perfect arrangement of the patents and applications and references of all kinds in the Patent Office. When it is remembered that the expenses of the Patent Office are not only paid by inventors, but that a surplus is each year turned into the treasury of the United States, it would seem there could be no question of the duty of Congress to provide sufficient force for the prompt transaction of the business.

Maritime Electrical Association.

A movement is on foot at Halifax, Nova Scotia, to form a Maritime Electrical association. It is not intended to conflict with established organizations, as the preliminary circular announces that "while it is felt that all those engaged in the electrical business in Canada should, if possible, belong to the Canadian Electrical association, there still remains a great need for an association of a more local character, whose place of meeting would be accessible to all its members, and which could discuss not only papers of a technical character, but also the questions arising from purely local circumstances." Among the promoters of the project are mentioned the following named gentlemen: E. T. Freeman of the General Electric company, Halifax; James Waddell, Prince Edward Island Electric company, Charlottetown, P. E. I.; F. A. Bowman, New Glasgow Electric company, and J. H. Winfield, Nova Scotia Telephone company, New Glasgow, N. S

Western Electrician.

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO.

TELEPHONE, MAIN 1746.

EASTERN OFFICE: 108 TIMES BUILDING, NEW YORK.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN is the only general electrical paper published in the West—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALLED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

HIGH WATER MARK

CIRCULATION, 20,000.

Four Years' Record of Electric Light Convention Advertising.

Litigation over trolley patents is becoming involved and complicated and there is evident confusion in the public mind over the present status of the Van Depoele patents. The bearing of the last decision upon this case cannot be determined until the complete record of the court is obtainable. So many conflicting statements have been made by those interested in the outcome of the controversy that an opinion upon the merits of the case would be based largely, if not entirely, upon conjecture.

The American Engineer wants to know why it is that, with all the technical schools preparing young engineers, one of the leading trunk railroads and a large car manufacturing concern have difficulty in securing satisfactory draughtsmen. Possibly the answer lies in the very fact that nearly all of our American schools undertake to turn out engineers exclusively and not draughtsmen. American students look upon mechanical drawing as a means to an end only, and very few of them are content to accept it as a life work. They are ambitious to do original work as soon as possible after graduation and often begrudge the longer or shorter time in which they are engaged as draughtsmen or assistants to older engineers. It is a fact that in this restless ambition and struggle for the prizes of the engineering profession many a man who might have been a first-class draughtsman all his life ekes out a precarious existence as a third-rate engineer. But the tendency is due to a deep-seated characteristic of American life—the keen ardor of meeting and solving the material problems of a continent—a trait which undeniably makes for progress.

Many cities now require street-railway companies to provide their cars with fenders or guards, but many corporations object on the ground that these so-called protective devices cause more accidents and inflict more injury than they prevent. It is contended that since the general adoption of electricity as the motive power for street railways the limit of speed attained has been raised considerably, and that this change has been accompanied by a corresponding increase in the number of accidents. It may be maintained that by far the greater part of these accidents are due directly to the carelessness of the victims and that a large percentage of the rest result from incompetency or carelessness on the part of the motorman, but occasionally there is an unavoidable mishap in which someone is injured, and then a cry is raised against the "deadly trolley" and urgent demand is made for fenders. Considerable litigation growing out of accidents of this description has occupied the higher courts in several states and several important points have been decided. According to late rulings it matters little whether the accidents are due to the carelessness and incompetency of employes or to defective and inadequate apparatus and protective devices.

In the case of Chandler against the Atlantic Coast Electric Railway company it was shown that an employe was engaged in the work of clearing away the dirt and refuse which had collected upon the company's track, and while so engaged was run down and killed by one of its cars. Negligence was charged against the company, in that it had failed to provide suitable fenders or guards for its cars, but the Supreme Court of New Jersey held that, even if it be conceded that such omission made the cars more dangerous to employes working upon the tracks than otherwise they would have been, no liability can be predicated upon such negligence. The court declares that it has been settled in this country and in England that if a servant chooses to enter employment involving danger of personal injury, which the master might have avoided, he takes upon himself the risk of all the hazards incident to the employment, the existence of which is known to him, or which are plain and obvious, and which he has no reason to expect will be counteracted or removed, and that no action will lie against the master for injuries to the servant resulting from such dangers. On the other hand, the contention was raised that the company was also negligent in knowingly employing an unskillful and incompetent motorman to operate the car which ran down the decedent. The Supreme Court pronounces this a good cause of action, as a master owes to his servants the duty of using reasonable care and prudence in the selection of their fellow servants, and, if he knowingly employs or retains in his service an unskillful or incompetent workman, he is responsible for injuries received by an employe through the unskillfulness or incompetency of such workman.

On the trial of an action by a traveler on a public street for injuries caused by the alleged negligence of a motorman employed by the defendant, the St. Paul City Railway company, evidence of the general incompetency of the motorman was allowed to be introduced, but the Supreme Court of Minnesota holds that this was error and that such evidence is inadmissible in such a case. The court declares that the company is liable, if at all, for the acts of its servant upon the doctrine that the principal or master must answer, or is responsible, for the acts of his agent or servant. If the motorman was negligent on this occasion, the company was liable, no matter how competent he was or how habitually careful he had been on other occasions. On the other hand, if he was not negligent on this occasion, the company was not liable, notwithstanding that he may have been incompetent or habitually careless on former occasions. If the complainant could offer testimony as to the general incompetency or prior negligent acts or omissions of the motorman, then, with equal propriety, the defendant, upon the issue of contributory negligence, might present evidence of the complainant's general carelessness, or of his negligent acts on other occasions. Likewise, private rules of the company, intended only for the guidance of its employes, and not known to the complainant, the Supreme Court holds, were inadmissible, in determining the company's liability. Finally, the company having omitted to call its motorman as a witness, although within reach and available, the Supreme Court holds that the trial court was, under the circumstances, justified in instructing the jury that, in weighing the effect of the evidence actually introduced, they were at liberty to presume that the testimony of the motorman, if introduced, would not have been favorable to the cause of the company.

In England the fever for municipal control of quasi-public enterprises has developed to an alarming degree. In one place an advantageous offer to establish a first-class telephone-exchange service at a cost of $200,000 was rejected and the city determined to put in its own plant. The only explanation offered is the statement that public opinion is favorable to municipal control of such enterprises.

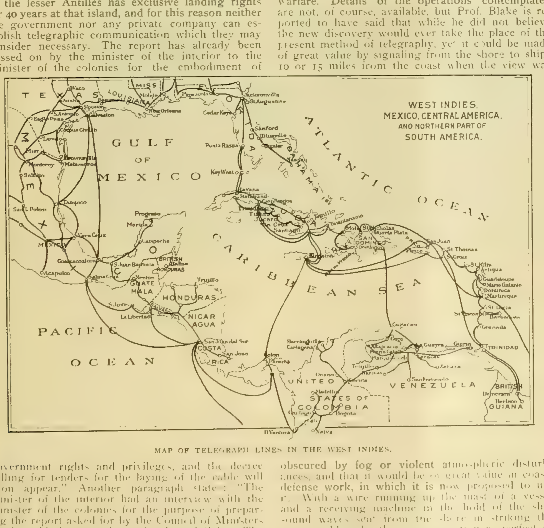
The restrictions placed upon the National Telephone company by the municipal government of London amount practically to supervision of the work of that company by the city. This tendency, it is claimed, has greatly retarded the growth of the business, and the recent check placed upon the city has been a source of congratulation on the part of the company. It would seem that it was not received with good grace by the municipality, however, for, according to the London electrical press, the corporation of London is still fretful about the recent decision that the postmaster-general may lay what telegraph or telephone wires he pleases in the streets of London, and may lease them to the National Telephone company or anyone else. The corporation has endeavored to raise a kindred feeling of resentment in the breasts of other local authorities. The resolution proposed at the annual meeting of the Association of Municipal Corporations declaring that "it is undesirable that the jurisdiction of the local authorities over telephone companies should be curtailed or interfered with" shows exactly what the grievance is, for no one can impartially argue that to give local authorities the right to veto the use of underground junction lines, as a connection between telephone subscribers and the trunk lines, can tend to improve or cheapen the telephone service. The use made by the corporations of their right of positive veto is said to be retarding the burying of the wires and the consequent improvement of the telephone service. But the city solicitor and his supporters say that they do not wish to have their privileges curtailed by the National Telephone company through the postmaster-general; that they do not want to be overridden by any of the telephone companies, and that the companies overran the roofs of houses as if they were their own private property.

The treatment accorded the telephone interests of this country is in striking contrast to the picture presented by our English contemporaries.

WAR NEWS.

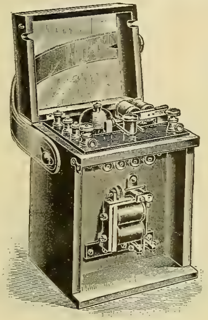
West Indian Cables.—In the present crisis in the affairs of the United States and Spain the accompanying map of the telegraphic cables and principal land lines in the West Indies, Florida, Mexico, Central America and the northern part of South America will be of interest. The direct communication between Cuba and the United States is by a duplicate Western Union cable laid from Havana to Key West and thence to Punta Rassa, on the west coast of Florida. This affords one means of communication, also, between Cuba and Europe by connecting with the numerous cables crossing the North Atlantic. However, if this route was closed to Spain, as it would undoubtedly be in wartime, there would still remain, as shown by the map, several means of connecting with the mainland of South America, and thus, by way of Pernambuco and the South Atlantic cables to Lisbon or Cadiz, reaching Spain. The Cape Verde Islands, where the Spanish torpedo flotilla is now said to be, form a station in the Lisbon-Pernambuco cable. Of course, in case of war, our government might undertake to cut the Caribbean cables, to isolate Cuba, but this would raise the vexed question of the neutrality of submarine cables, which does not appear to be well settled by international law. The existing commercial rate to Havana is 40 cents a word; but the press rate, which is practically the only one used, is five cents a word to that city. To stations in Cuba beyond Havana and to other West Indian stations, messages are sent either by way of Havana or by way of Galveston, the latter city being an important connecting point in the network, as shown by the map.

If Spain is allowed to keep Cuba, which seems unlikely, it will undoubtedly want more direct communication than the roundabout routes by the United States or South America. As already noticed in the Western Electrician, the direct-cable project has taken a definite form, but for several reasons it will probably never materialize. An interesting insight into the views of the Spanish themselves is given by the following from recent issues of El Imparcial of Madrid: "The Ministry of the Interior has reported favorably on the tender for the laying of a direct cable between the peninsula and the island of Cuba. The cable will land at Cadiz, Santa Cruz de Tenerife, Nieques (an island situated 15 kilometers to the east of Porto Rico), and finally at Havana. The cable will not, contrary to the interest of the nation, be laid to St. John, Porto Rico, as the company owning and working the cables in the lesser Antilles has exclusive landing rights for 40 years at that island, and for this reason neither the government nor any private company can establish telegraphic communication which they may consider necessary. The report has already been passed on by the minister of the interior to the minister of the colonies for the embodiment of government rights and privileges, and the decree calling for tenders for the laying of the cable will soon appear." Another paragraph states: "The minister of the interior had an interview with the minister of the colonies for the purpose of preparing the report asked for by the Council of Ministers on the cable between the peninsula and Cuba. The report will deal with two proposals, one being for the construction of the direct cable, and the other for a branch cable from Havana to Haiti, to connect there with the French system." Another issue of the same paper says: "The news that the ministers of the colonies and the interior have been entrusted by their colleagues in the council with the decision regarding the matter of the direct cable to Cuba, and, further, that there are two proposals to be dealt with, viz., (1) offering to construct a direct cable, and (2) a branch cable from Havana to Haiti, there to be connected to the French system, has given rise to certain fears, which we find to have serious foundations, as by the latter scheme we should merely be ridding ourselves of the control of our communications by Great Britain and the United States to transfer it to the French. The Nacional states if the direct cable is not to be laid, rather than allow all the traffic to be handed to the French Cable company, let the state of affairs remain as at present. Our contemporary asks for more light upon the subject from the ministerial press, and we join in the demand, as we endorse their opinion."



MAP OF TELEGRAPH LINES IN THE WEST INDIES.

Wireless Telegraphy.—It is possible that one of the innovations of the war, if war there be, will be the use of a system of wireless telegraphy between warships or between ships and the shore. Commodore Schley is mentioned as an officer who is familiar with the naval tests of the new system, and who is said to favor it. Prof. L. I. Blake of Kansas University has also paid much attention to the practical possiblities of wireless telegraphy in warfare. Details of the operations contemplated are not, of course, available, but Prof. Blake is reported to have said that while he did not believe the new discovery would ever take the place of the present method of telegraphy, yet it could be made of great value by signaling from the shore to ships 10 or 15 miles from the coast when the view was obscured by fog or violent atmospheric disturbances, and that it would be of great value in coast-defense work, in which it is now proposed to use it. With a wire running up the mast of a vessel and a receiving machine in the hold of the ship sound waves sent from the shore in striking the wire would make the communication as perfect as could be desired.



WIRELESS TELEGRAPHY. THE RECEIVER.

One type of receiver for telegraphic signals without wires is shown by the cut. It was displayed at a meeting of the Institution of Junior Engineers at London on March 12th by Leslie Miller, who gave an exhibition of telegraphing without wires from one end of the room to the other. He employed the simple receiver which is herewith illustrated. The coherer is suspended in the middle of a stretched wire, and two small rods, with a screw thread on them, play over the wire like a fiddle-bow over the strings. These rods are attached to the armature of a bell, connected in the secondary circuit of the relay (seen in the front of the case), whose primary circuit is in series with a single dry cell and the coherer. A second cell is used in the secondary circuit. This form of decoherer has the advantage that the decohering action begins directly the armature moves, and continues during its whole travel to and fro. The coherer itself merely consists of a small ebonite cup, inside which the two wires on which it is suspended almost meet, the gap being bridged over by nickel filings. During the experiments a simple transmitter was employed, consisting of a four-inch solid brass ball, with a one-inch brass ball on either side. The spark-gap was comparatively short. Signals were transmitted from one end of the room to the other, and the demonstration was pronounced successful in every particular. Among the prominent men in attendance was Hiram S. Maxim, who displayed great interest in the experiment.

The system has recently been successfully applied to permanently establish telegraphic communication for the British War Office between Lavernock Fort and the fort on the Flat Holm (in the Bristol Channel), a distance of 3¾ miles. On the mainland, opposite the island, an ordinary pole line, three-quarters of a mile long, with a heavy copper wire, has been erected; the ends of the circuit terminate in the sea. On the island there is a similar line established about half-a-mile long. The transmitting apparatus (on each line) consists of a contact breaker worked by a small dynamo, running at 3,000 revolutions per minute, and giving 250 makes and breaks per second, corresponding to the middle C note; the intermittent current is given by 10 dry cells. An ordinary Morse key interrupts the circuit, and the receiving apparatus is an ordinary telephone receiver. The installation has been carried out under the direction of Mr. Gavey, assistant engineer-in-chief to the Postoffice Department, assisted by Mr. Taylor. It has been found impracticable to maintain communication between the two forts by means of a cable, as the latter was continually broken by the anchors of the shipping.

Electrical Wiring in Harbors.—The work of electrically equipping all the forts in New York harbor is about completed, and the work in the other important harbors along the Atlantic Coast is also well advanced. Submarine cables and underground wires have been laid connecting all of the New York forts with headquarters and with each other, so that instant communication by both telephone and telegraph will be possible. A large amount of wire has been put in place for connections with submarine mines, and the dynamos have been placed for the searchlights at all the forts. The big 60-inch searchlight which was used on top of the Manufactures building at the World's Fair, and has since been at Sandy Hook, has been moved to Fort Monroe. But the dynamo and wires used with it are still at Sandy Hook, and a new projector will be put up there. There are many searchlights in different parts of the country which can be secured, and all that are needed will be speedily put in place. There is a searchlight in readiness at Fort Wadsworth, and the electrical equipment there is completed. About 60 miles of wire have recently been contracted for, and much of it is for submarine mine connections. A high quality of protected cable will be laid and the mines can be quickly put in place and connected therewith. A number of Battery boatmen have recently been hired to assist in this work, as it requires experience to handle a small boat on the rough water frequently found at the Narrows and in the ship channel off Sandy Hook.

A dispatch from Boston, dated April 8th, gave the news of the work at that point: The first steps in the actual work of completing the defense of Boston harbor by means of submarine mines were taken this morning, when a score of expert electricians left the city for Long Island Head, taking with them many coils of insulated wire cable and considerable electrical apparatus. Long Island, from which will be controlled the mines in Broad Sound, will be first arranged and then will come the work at Fort Warren for the mines in the main ship channel. The shore wires will be carried down to the water in the rear of the forts and the submarine cable led around to that point. With the shore connections and apparatus in place everything will be ready for action as soon as the engineer corps places its mines and lays its submarine cables. This work will not take over 48 hours, for the mines themselves have been ready for some time at Fort Independence, Cast Island, while all needed cable and connections are also at hand.

General Greely's arrival is reported from Savannah. In addition to the electrical work, the general is in charge of the new coast and gulf line signal system, by which communication will be established between ships near the coast and the Navy Department. An allotment of $20,000 for each state has been made from the emergency fund for erecting tall signal poles at the chief stations, the construction of the semaphore house stations for signal purposes, and other signal appliances.

From Philadelphia it is reported that the services of the Philadelphia Electrical Division, composed of practical electricians organized to serve the government if needed, have been accepted by Major Raymond, U. S. A. The electricians are on waiting orders to assist in laying submarine mines in Delaware Bay and other electrical work in connection with the defense of the city.

[*Continued on page 231.*]

DEVELOPMENT OF THE TELEPHONE FIELD.

Growth of Independent Movement in the South.

[Special correspondence of the Western Electrician.]

The opposition exchange started at Shreveport, La., three years ago has met with great success, the company now having 505 subscribers, while the Bell exchange has only a few subscribers.

The independent exchange installed at Monroe, La., two years ago continues to increase its business and now numbers 180 subscribers. The old company has retained very few subscribers and some of these have recently deserted it.

The People's Telephone company of Jackson, Miss., which came out in opposition to the Bell in August, 1896, began with 100 subscribers, against the old or Bell company's list of 144 subscribers, has steadily increased its list and now includes 340 instruments at Jackson and has connection with a large number of towns and villages within 40 miles of its exchange. The old company is rebuilding its line work and has under construction a new line to connect Jackson with Vicksburg, the old line to the latter point being almost useless.

The Yazoo City (Miss.) Mutual Telephone company, which began one year ago, has more than twice as many subscribers as the Great Southern (Bell) company ever had, and by the terms of the contract its subscribers agree to use no other service than the Mutual, so that it looks as if the Bell people will be forced out rather than the home company.

The Citizens' Telephone company of Crystal Springs, Miss., which has installed an independent exchange at Vicksburg, began its service September 1, 1897, and now has over 350 subscribers connected with its exchange, including every business firm in the city using a telephone, excepting one stable and one cotton broker. The Cumberland (Bell) company, finding that the new exchange was rapidly depleting its list of subscribers, is making an active canvass of the town, offering residence 'phones at $6 per year as against the former rate of $36 per year. The Citizens' exchange is connected with Yazoo City and intermediate points and will probably build a line to Jackson, Miss. The Citizens' company has just completed rebuilding its entire plant at Crystal Springs, Miss., and has moved into its new quarters, having erected a small building in the center of the business district for the accommodation of its business. Its list of subscribers has increased rapidly. By its long distance lines it is connected with a large number of towns and villages, including the more important points in the surrounding counties.

The Canadian and Cheyenne Telephone company of Canadian, Texas, has been formed, with a capital stock of $2,500, by George Gerlach, Robert Moody and D. J. Young.

At Snow Hill, Md., C. J. Purnell, W. S. Powell, W. F. Johnson, J. P. Moore and others have incorporated the Worcester Telephone company, with a capital stock of $2,500.

A charter has been granted the West Plains, Mo., Telephone company, with a capital stock of $25,000, by D. W. Reese, Charles H. Gale, F. O. Hines and others.

C. O. and H. J. Patton, Lewis Schultz & Co., William A. Patton, Jr., and others have incorporated the McFall (Mo.) Telephone company, with a capital stock of $1,000.

Automatic Telephone Service.

In several large cities where opposition to the Bell company has been manifested local capitalists have been attracted by the automatic telephone system that has been developed during the last 10 years. When first introduced it was crude and in some respects not well adapted to the general work required of exchanges, but experience has pointed out these defects, and as they have appeared they have been carefully studied and corrected.

Now, it is claimed, the Automatic Telephone Exchange company of Washington has its apparatus in practical operation in the following-named cities: Augusta, Ga, Aiken, S. C., Maryville, Kas., Morgantown, N. C., Albuquerque, N. M., Amsterdam, N. Y., Manchester, Ia., Trinidad, Colo., Rochester, Minn., Perry, N. Y., Princeton, N. J., Coudersport, Pa., Albert Lea, Minn., Albion, N. Y., La Porte, Ind., Chester, Ill.

The exchange at La Porte, which was the first of the kind in the world, was the subject of an illustrated article in the Western Electrician of November 12, 1892. The apparatus employed in the automatic system had been illustrated and described in detail in this journal on August 6th of the same year. By referring to these numbers and comparing them with the illustrations accompanying this article, some idea of the advancement that has been made will be gained. Fig. 1 shows the exchange equipment employed at Trinidad, Colo., the board having a capacity of 200 subscribers. A much larger equipment is represented in Fig. 2, which illustrates the apparatus employed at Augusta, Ga., with capacity for 1,000 subscribers.

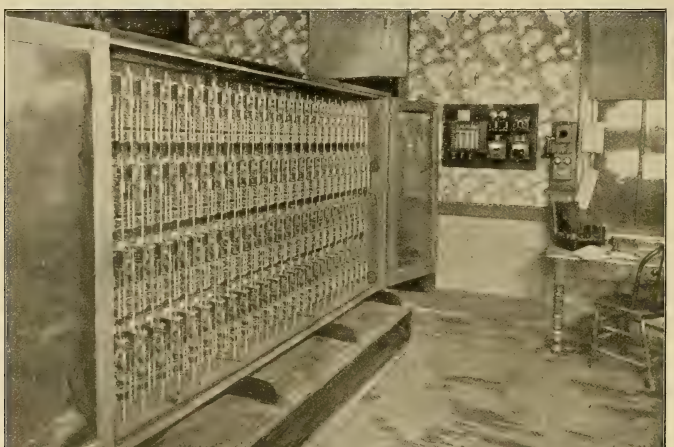


FIG. 1. AUTOMATIC TELEPHONE SERVICE.—EQUIPMENT OF EXCHANGE AT TRINIDAD, COLORADO.

It should be borne in mind that the "exchange," as the term is generally employed in telephony, is eliminated from the service in the automatic system. The latter connects each subscribers' telephone with an apparatus at a central point which possesses the functions of a complete switchboard. The apparatus bears no resemblance in form to a switchboard, but so concentrates in itself the terminals of the lines of other subscribers that the caller, by simply touching the figures designating the number wanted, connects the latter line with his own, ready for conversation in absolute secrecy, and, by hanging up the telephone after use, restores all parts to normal condition. Each subscriber's line terminates at the central station in a similar miniature switchboard or terminal apparatus, occupying but little space, all being connected and concentrated in a glass case where, free from dust or disturbance, it is claimed, they may remain for years, giving better and better service as the contacts wear to greater exactness of surface touch.

The system as developed is an interesting and attractive combination and has won commendation from many practical exponents of modern telephony.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

Two tramp linemen stole about 175 pounds of copper wire from the Iowa Telephone company at Boone, Ia., and disposed of it at a junk shop. They were captured, tried and convicted, and sentenced to 15 days in jail.

C. G. Cockerill will build a telephone line from Jefferson, Ia., to Grand Junction at once. Mr. Cockerill has just bought the Jefferson Telephone company. He owns all the lines built by that company north and east of Jefferson.

F. G. Barrows is an applicant for a telephone exchange at Fergus Falls, Minn. The Minnesota Central Telephone company wants a long-distance franchise there.

John Gay has been appointed manager of the Northwestern Telephone Exchange company at Winona, Minn., succeeding Mr. Griffin, the present manager, who will be transferred to some other point.

An all-night telephone service will soon be established at Glenwood, Ia.

For some time past H. C. Van Hovenberg of Eau Claire, Wis., has been objecting to the Eau Claire Telephone company locating a telephone pole in front of his property. No arrangement could be made between them, and the company quietly set the pole at one o'clock in the morning. Work was finished long before anyone was astir. It is said legal measures will be taken to compel the removal of the pole.

The Western Telephone Construction company is an applicant at Stevens Point, Wis., for a long-distance connection.

The American Bell Telephone company has bought at Menominee, Mich., 20,000 telephone poles, costing $75,000. This is the largest deal in telephone poles ever made in that section.

The telephone service in Tacoma, Wash., has been materially improved by the new plant that has just been put in.

The Iowa Telephone company is seeking to increase its subscribers at Bedford, Ia. It will reduce rates when 30 new names are added.

T. F. Robinson of Tracy, Minn., is an applicant for a telephone franchise at Windom, Minn. Mr. Robinson is now putting in an exchange at St. James.

Forty instruments have been subscribed for in the local telephone exchange just organized at Glenwood, Minn. M. A. Woollan, P. Peterson and C. L. Peterson will form a company for the exchange.

The American Telephone and Telegraph company has connected with La Crosse, Wis., over the wires of the Wisconsin Telephone company and now gives La Crosse long-distance service.

The new telephone exchange for Marshfield, Wis., is to be rushed as fast as possible. The survey has been made.

The Rocky Mountain Bell Telephone company disregarded the temporary injunction secured by a

stockholder in the Electric City Telephone company at Great Falls, Mont., which it has just absorbed, on the ground that it was inoperative, being served after the sale had taken effect. At the hearing this view was upheld and the injunction dissolved. George H. Stanton, a stockholder, then brought suit, alleging that the independent company was in good shape when the deal was made and not losing money, but would have paid a fair dividend. He charged that the sale was illegal. A temporary injunction was issued to prevent the Bell company from discontinuing the service, and the matter will be argued in court.

The New Prague and Veseli Telephone company has been incorporated to build a telephone line in Minnesota between those places.

The Northwestern Telephone company and the Cedar Valley Telephone company will have a common office at Nashua, Ia.

The Rosendale, Ladoga, Rogersville and Eldorado Telephone company has been organized to connect those towns in Wisconsin.

C. E. Thew, Jr., who has been manager of the local telephone company in Menomonie, Wis., will go to Ashland, Wis., to work for a telephone company there.

The town of Fairbanks, Ia., will vote soon on granting a telephone franchise to J. E. Shannon.

A stock company will be formed to put in a telephone exchange at Mason City, Ia.

The Mississippi Valley Telephone company expects to spend $10,000 for labor in putting in its new exchange at Muscatine, Ia. Work is to be begun very soon.

A new telephone company will be formed in Stillwater, Minn., to put in a telephone exchange. The council is considering its application for a franchise.

A telephone line is to be built between Preston, Minn., and Prairie Queen, by D. R. Thatcher, William Fishbaugher and John Berning of Prairie Queen.

Municipal Telephone Exchange.

Rather than accept the offer of the National Telephone company of England to spend from £30,000 to £40,000 in reconstructing the Huddersfield telephone system and making it as perfect as present experience renders possible, the general purposes committee, consisting of the entire corporation of that city, has adopted the recommendation of the electric-lighting committee that the telephone system should be placed under municipal control. The sole inducement would appear to be that Huddersfield wishes to possess the first municipal telephone system. A contemporary which sympathizes with the idea says that local-government control of telephone system, however, must not be placed on the same footing as that of baths and washhouses, electric light and waterworks, or even street railways.

Cost of Telephone Litigation.

The Australian Building, Engineering and Mining Journal says: "Since 1880 the American Bell Telephone company has spent £469,685 in litigation. This expenditure to uphold patents which give an incomplete monopoly is large—but America is America."

Long-distance Telephony in Canada.

[From the Canadian Electrical News.]

The first attempt of the Bell Telephone company of Canada to establish a long-distance service was made in 1881 by the construction of a single iron-wire line between Toronto and Hamilton, then considered quite an achievement, and the line was well patronized. Within three years 855 miles of poles and 1,500 miles of wire were constructed by the company, but so rapidly did conditions change, that even in this short time this type of line was found inadequate to the requirements of a growing business.

In 1885 copper wire was substituted for iron wire, affording better results. The introduction of the electric light and trolley, however, soon forced upon the company another and a more radical change, and metallic circuits had to be adopted upon all principal lines. This change, begun in 1885, was carried on as fast as circumstances would allow until all the principal lines of the company were made metallic, or, in other words, two wires were necessary to transmit a satisfactory conversation where one would suffice before the introduction of electric cars.

The extension of the system, in the meantime, went on apace, until, at the end of 10 years, the company had in operation 4,484 miles of pole line and 13,148 miles of wire in its long-distance service, and at the present time they have in the provinces of Ontario and Quebec 6,095 miles of poles, bearing 16,567 miles of wire.

Connections have been established with the extensive long-distance system of the American Telegraph and Telephone company and affiliated companies in the United States at Newport, Vermont, St. Albans, Ogdensburg, Buffalo and Detroit, affording a system of direct telephonic communication as far south as Virginia and Tennessee, and from the cities and towns of the Atlantic seaboard westward to Nebraska.

The difference in the cost of the first long-distance line of 1881 and the long-distance line of to-day affords one of the serious problems in finance which the company has to meet. It is not a mere matter of change; it is a revolution requiring absolutely new and far more expensive construction. In 1881 a No. 9 iron wire (288 pounds to the mile) was the best in use. To-day most of the construction is of two copper wires (which together weigh 532 pounds to the mile). Formerly 32 poles to the mile were sufficient, but with the introduction of copper, in order to reduce the strain upon the wire, 40 poles to the mile are used. The poles have to be set deeper in the ground and more carefully stayed, all of which greatly increases the cost.

The long distance central office equipment of to-day is much more expensive than it was 10 years ago, improvements having been made to facilitate the work of operating and to secure the best results in communications. The astonishing results which the long-distance telephone service of to-day affords is due as much to the improvement in instruments, switches and other apparatus, and to the system upon which these are employed, as it is to the improvement in the lines.

Telephone Service in Germany.

In view of the growth of the German electric railway lines, and the extensive use of the single-wire system for the telephones in that country, it is remarkable that the railway and telephone interests have not come more into collision. An incident is reported from Elberfeld, says the London Electrician, where the telegraph administration has protested against the running of the Neviges-Velbert electric railway, as it disturbs the telephone traffic in the district, and it requests the company which owns the line to place the telephone lines between Elberfeld and Neviges (a distance of five miles) underground. It is certainly high time that the German telegraph administration decided to adopt metallic circuits, and to place them underground in the towns, for at present the service is far from perfect, and it is notably bad in the manufacturing district of Rhenish Prussia and Westphalia, at the center of which Elberfeld is situated. The telephone administration in Germany does not treat subscribers well in the matter of instruments. It has decided to supply subscribers with only one receiver instead of two. If the subscriber wishes to have a second receiver, he must buy it for 10 shillings from the administration, which will "keep it in order" for him for a consideration. It is true that one German instrument of the pattern used by the administration, weighing as it does 1½ pounds, is bigger than two English ones, but yet the rule appears hardly fair. If the subscriber wishes a bell different to that offered him he has to buy it, and a desk instrument, in place of the usual wall set, costs five shillings a year extra. If he objects to having the bell, battery box and transmitter on the same wall, he has to pay a supplementary charge for the use of his own second wall. The only redeeming feature, in fact, of the German telephone service is its very low subscription rate.

FIG. 2. AUTOMATIC TELEPHONE SERVICE.—1000 SUBSCRIBERS' EQUIPMENT AT AUGUSTA.

Kansas Enterprise.

Manhattan leads the world in one thing, and that is its telephone system. Stockholm, Sweden, has long been in the lead with a record of one telephone for every 20 people, but Manhattan has one for every 13 people. An average of 1,500 calls a day from the 235 telephones keeps Miss Mabel Crump busy, while a proportionate number of calls are answered by Miss Ada Howe during the night. In large cities one operator has charge of but 100 telephones, but Manhattan girls are smarter than the average, and they do the extra amount of work nicely.—Manhattan Mercury.

The Wareham & Wood Telephone company to-day put in a new 200-wire cable. There are now 125 'phones in use in the city and new subscribers are being added daily. The construction force is now within three miles of the city, and by the middle of the coming week Chanute will have telephone connection with Humboldt, Iola, La Harpe, Moran, Bronson, Uniontown, Redfield and Fort Scott. Chanute has every reason to be proud of its telephone system, and Wareham & Wood, the owners, are to be complimented upon their enterprise and hustling proclivities.—Chanute Tribune.

Telephone Competition for Philadelphia.

Another attempt will be made to establish a rival to the Bell company in Philadelphia. An ordinance was introduced in the Common Council of that city on Thursday, April 7th, by the terms of which the Drawbaugh Telephone and Telegraph company is authorized to lay conduits, erect poles and conduct a local telephone-exchange business. This company applied to councils for privileges in the spring of 1894, at which time two other telephone ordinances were under consideration, one of them being that of the Mutual Automatic Telephone company. All were referred to the electrical committee. The subsequent history of the Mutual company is familiar to telephone men.

The Drawbaugh company has persisted in its efforts to secure a franchise, and although its petition was not granted in 1894 nor in any of the subsequent councils, the promoters of the enterprise continue to press their claims with unabated vigor. The officers of the Drawbaugh Telephone and Telegraph company are: President, J. F. Stokes; treasurer, John D. Ford; secretary, Charles A. Gladding; general manager, Brinton N. Newcomb; directors, J. F. Stokes, Monroe Smith, John D. Ford, William O. Hempstead, Charles A. Gladding, Brinton N. Newcomb and Samuel L. Kent.

Holtzer-Cabot Telephone Receivers.

The new metal head receiver manufactured by the Holtzer-Cabot Electric company of Brookline, Mass., is shown by the accompanying cut (Fig. 1). The head or cup of this receiver is of metal, which is screwed on and firmly attached to the metal tip, which also carries the compound bar magnets; the rubber shell is simply slipped over these and held in place by a screw at the farther end. The adjustment between the tip and diaphragm, it will be seen, is permanent and cannot be affected by changes of temperature. This is claimed to be a more practical form of receiver than any of the adjustable-head styles on the market. Inexperienced men with more inquisitiveness than practical knowledge of telephonic conditions can, by "just altering the adjustment a trifle," throw them out of order or seriously impair their efficiency. This contingency is

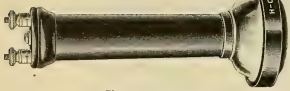

Fig. 1.

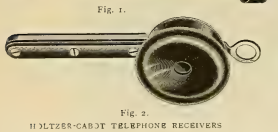

Fig. 2.
HOLTZER-CABOT TELEPHONE RECEIVERS

provided against in the construction of the Holtzer-Cabot metal head receiver by making the adjustment at once perfect and permanent.

The Holtzer-Cabot company also manufactures standard and pony receivers, using the best hard rubber shells of sufficient thickness to insure their not varying materially under changes of temperature. The company makes a strong point of the fact that by its method of construction it positively prevents dust from falling down and accumulating on the magnet tip. It also manufactures a bi-polar watch case receiver and a single-pole watch case receiver with handle (Fig. 2). The latter is claimed to be the most convenient form of receiver made. These styles are fully described in a new telephone catalogue which the Holtzer-Cabot Electric company has just issued.

COMMUNICATION.

The Firman Patent.

To the Editor of the Western Electrician:

Noting the communication of Barton & Brown in your issue of the 2d inst., entitled "Firman Switchboard Patent Sustained," I will say that the case referred to is one of two suits instituted against the Capital Telephone and Telegraph company by the Sunset Western Electric-Bell combination in October, 1895, or about the time we entered the telephone business in Sacramento.

The first, which was upon the use of the Watson automatic telephone switch upon our instruments, was dismissed at complainant's cost.

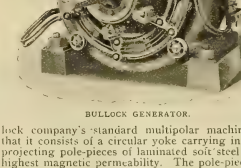
This one was upon the use of the Perrin multiple switchboard, and I will say that the decision as rendered does not concern us in the least, as we never have, since the commencement of business, operated under anything but the "trunking system," which is open to the free use of the public. While our original board was constructed for either multiple or trunking work, all recent additions have been purely trunking sections; hence we must operate under that system and cease to operate under the multiple. The decision simply restrains us from using something we do not wish to use and would not use if we could.

As for an accounting, that was waived in open court by the Bell attorneys, there being no showing whatever for damages. They pay their own costs in this case.

CAPITAL TELEPHONE AND TELEGRAPH COMPANY,
M. J. Dillman, vice-president and general manager.
Sacramento, Cal., April 8, 1898.

Bullock Generator.

The Bullock Electric Manufacturing company is the manufacturer of the generator shown by the cut. This machine is designed for direct connection to engine. The general design is similar to the Bullock company's standard multipolar machines, in that it consists of a circular yoke carrying inwardly projecting pole-pieces of laminated soft steel of the highest magnetic permeability. The pole-pieces are cast-welded into the frame, thus forming a more substantial joint, both mechanically and magnetically. This generator is built in six standard sizes, ranging from 25 to 200 kilowatts.



BULLOCK GENERATOR.

These generators are compounded to compensate for drop of potential in the line. The shunt and series coils are wound on separate forms, and are removable at will. The field coils are so wound that they are open for the circulation of air, and perfect ventilation is assured. All the compound

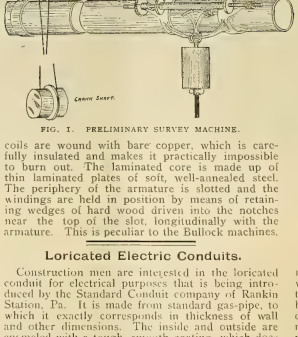


FIG. 1. PRELIMINARY SURVEY MACHINE.

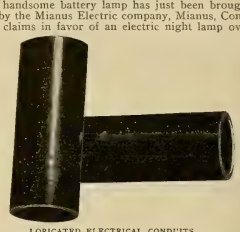
coils are wound with bare copper, which is carefully insulated and makes it practically impossible to burn out. The laminated core is made up of thin laminated plates of soft, well-annealed steel. The periphery of the armature is slotted and the windings are held in position by means of retaining wedges of hard wood driven into the notches near the top of the slot, longitudinally with the armature. This is peculiar to the Bullock machines.

Loricated Electric Conduits.

Construction men are interested in the loricated conduit for electrical purposes that is being introduced by the Standard Conduit company of Rankin Station, Pa. It is made from standard gas-pipe, to which it exactly corresponds in thickness of wall and other dimensions. The inside and outside are enameled with a tough, smooth coating, which does not crack when the conduit is bent, and no lining is used. The tubes are in 10-foot lengths, with a coupling on one end and a thread on the other. The interior of the tube is smooth. If need be, light wall tubing can also be furnished, when specially called for. This loricated conduit, it is claimed, excels in the ease and economy with which it can be installed, and its quality is attested by the fact that it has been approved for use by the National Board of Fire Underwriters. Robert Garland, the treasurer, announces that the material has recently been installed in the following buildings: Post-office, Washington, D. C.; Carnegie Library, Homestead, Pa.; Carnegie Library, Lawrenceville, Pittsburg; Commercial National Bank, Monongahela National Bank, Joseph Horne & Co., Pittsburg Leader, Daub and Murtland buildings, Pittsburg; and the Eleventh Ward School, Allegheny City. The company is busy on a variety of contracts, and will be glad to receive inquiries and give estimates or other information.

Mianus Battery Lamp.

A handsome battery lamp has just been brought out by the Mianus Electric company, Mianus, Conn. The claims in favor of an electric night lamp over



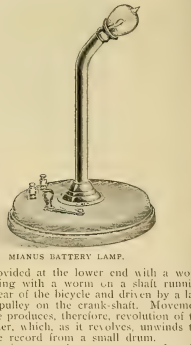
LORICATED ELECTRICAL CONDUITS.

an oil lamp, which is smoky, emits carbonic acid and consumes the oxygen of the air, are undisputed. This electric lamp, which can be placed near the clock on a table, has a switch attached to its base and can therefore be easily manipulated. Dry batteries are used for the lamp, which will, it is said, last a year without attention. The box has binding-posts, so that wires can be run from posts on the lamp to posts on the box. The lamp may be used as a hall light or in any place where an occasional light is required.

Preliminary Survey Machine.

The demand for a speedy method of making preliminary surveys without the usual array of engineers and instruments seems to have been met by a device recently invented by John Riddell of the General Electric company, Schenectady, N. Y., and entitled an instrument for delineating topographical peculiarities and measuring and recording distances. It is small and compact and may be mounted on a bicycle or upon any wheeled vehicle drawn by horses or pushed by hand or foot. It is shown in Fig. 1 mounted on the horizontal upper bar of a bicycle and consists, briefly, of a vertical revolving cylinder carrying the record and a marker moved upwards and downwards by the inclination upwards or downwards of the upper bicycle bar.

The metal cylinder carrying the paper for the record is provided at the lower end with a worm wheel engaging with a worm on a shaft running toward the rear of the bicycle and driven by a lace belt from a pulley on the crank-shaft. Movement of the bicycle produces, therefore, revolution of the record cylinder, which, as it revolves, unwinds the paper for the record from a small drum.



MIANUS BATTERY LAMP.

The marker is mounted on a nut on a threaded vertical rod. The lower end of the rod is fastened to a horizontal disk free to move clockwise or the reverse. Beneath the disk, and just clearing it on each side, are two smaller disks, at each end of a toothed sleeve, and revolving vertically. Through the sleeve passes the disk-shaft provided with a gear wheel meshing into a small gear on the main shaft driven from the crank axle.

Suspended beneath the bar of the bicycle, and consequently beneath the entire machine, is a pendulum having at its upper end a toothed quadrant meshing into the teeth of the sleeve on the shaft carrying the vertical disks. As the small disks revolve in the same direction, one in contact with the

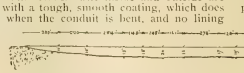


FIG. 2. PRELIMINARY SURVEY MACHINE.

large horizontal disk revolves it clockwise and causes the marker to ascend, the other counter clockwise depressing the marker. The nearer the center of the large disk the small disk comes, the faster the former moves and the sharper the angle described by the marker.

It will be seen that the pedulum hangs vertically whatever be the angle of inclination of the bicycle. If the machine is ascending the horizontal bar assumes an obtuse angular position to the pendulum, the rear vertical disk is brought beneath the horizontal disk and the marker moves upward; if a declivity is descended the angle of the bar and the pendulum becomes acute, the forward disk comes into play and the marker moves downward. On the level both vertical disks are out of contact with the horizontal disk and the marker records a plain horizontal straight line.

A part of a record is shown in Fig. 2. The number of feet above the level is shown by the horizontal line, the distance traveled by the length of the record. It is part of a record made on a wheel ridden from the gates of the General Electric company's factory to the main street of Schenectady.

The value of a device of this character will readily be appreciated by military, civil and railroad engineers. At present if a piece of road requires survey, or the lay of the land in a certain direction is to be ascertained, a system of survey is necessary involving considerable time and labor. Recent mention was made of the rapidly accomplished survey of 49.22 miles in 19 hours by means of a bicycle and compass. The mapping of the line surveyed occupied several hours additional labor. With a device of the character mentioned the completed topographical profile could have been ascertained in the time taken to propel the wheel over the length of the road surveyed.

Illinois Electric Company.

A new corporation which has recently opened offices and salesrooms at 239 Madison street, Chi-

Frank E. Healy.

Lemuel K. Cushing.

Carl Keith.

cago, will be known as the Illinois Electric company and will make an urgent bid for popular favor. The personnel of the corporation is a happy combination of utility and ability, consisting of F. E. Healy, president, L. K. Cushing, secretary, and Carl Keith, treasurer. All have seen service in the business in one of the largest supply houses in the West.

Mr. Healy, the president of the company, has been "brought up" in the electrical-supply business. Mr. Cushing, the secretary, is no new comer, besides he is a member of an electrical family and enjoys a tutelage from no less a personage than Prof. Elisha Gray. The telautograph had no sooner acquired a practical standing than Mr. Cushing, who had assisted in the development, was deputized to exhibit the invention, and in this capacity traveled throughout the country. Of late he has been engaged in handling electrical supplies.

Treasurer Keith started at the bottom of the ladder, and it is quite evident that his efforts to acquire knowledge of the business have been successful. He possesses a keen insight into financial matters, which coupled with his experience in practical service, will prove valuable to the already popular combination.

These energetic young men have already secured the agency for N. I. R. rubber-covered wires and cables, the high quality of which is well known, and the Edison, Jr., improved incandescent lamp.

Thermostatic Cable Endorsed.

The Gamewell Auxiliary Fire Alarm company of New York has completed a thorough examination of the Montauk Multiphase Cable company's system of thermostatic cables, and Joseph W. Stover, president of the Gamewell company, has notified the Montauk company of the result of these investigations in a letter containing the following statement:

Herewith we send you formal acceptance of your proposal for furnishing us with your "multiphase electric cables." After full consideration, we have come to the conclusion that we will find, through the use of your cable, something long known to be desirable but hitherto impracticable, viz. a device which we can safely use for the purpose of combining thermostatic fire-alarms with our auxiliary system of connection with public fire-alarm telegraphs.

The Montauk Multiphase Cable company originated and developed this new line of cables which, when installed for interior electric service, gives property owners and insurance companies an additional protection against loss by fire. This system makes wires sensitive to dangerous heat or flame so that they will automatically notify any point desired of the existence of such heat or flame at its inception. The value of these cables is in the fact that they are not required to be especially installed for this purpose, but, on the contrary, are used in buildings for all of the interior electric work required, and every additional wire or cable installed under the Montauk cable system is continuously thermostatic, and results in giving protection from loss by fire, although installed for purposes of an entirely different nature. Not only is the property holder benefited by gaining additional protection for life and property, but the insurance companies have an additional guarantee against loss through the use by the public of this system. The company places great value upon the endorsement and adoption of the system of interior, automatic, thermostatic, electric cables by the Gamewell Fire Alarm company and its auxiliary companies, as the Gamewell company is the parent of the present extensive fire-alarm system which is in use in over 700 of the largest cities of the United States, and has furnished more than 90 per cent. of all the fire-alarm apparatus used in the United States and Canada. The Gamewell company's experience extends over 50 years, during which it has tried many ways to give reliable and quick notification of fire. It is therefore with satisfaction that the main points brought out in the letter to the Montauk company are seen to be that this cable has received full consideration by the Gamewell people and that they have come to the conclusion that an automatic protection can be safely given in connection with their fire-alarm system where no other device has ever been relied upon; in other words, they are willing to rely upon the burning of this cable to close the circuit and thus automatically call out the forces of the fire department through their auxiliary system.

Canadian Electrical Association.

The executive committee of the Canadian Electrical association is making arrangements for the annual convention which is to be held in Montreal on Tuesday, Wednesday and Thursday, June 28th, 29th and 30th. The headquarters of the association during the convention will be at the Windsor Hotel, where the business sessions and the annual banquet will also be held.

The programme recommended by the local committee of arrangements was adopted, and is as follows:

First Day.—Executive meeting 9.30 to 10 a. m.; session, 10 a. m. to 1 p. m.; session, 2 to 5 p. m.; 7.30 p. m., trip around Mount Royal by special Park and Island cars, afterward ascending incline railway to lookout on mountain to view the city under illumination.

Second Day.—Session, 9 to 12, noon; cabs and buses from Windsor Hotel at 1 p. m. to visit the Bell Telephone company's new building, the street railway company's power house and the power house and works of the Lachine Rapids Hydraulic and Land company, returning to the city at 7:30 p. m.; 9 p. m., annual banquet of the association at Windsor Hotel.

Third Day.—Session, 9 to 12 a. m., election of officers and visit to McGill University; 1:30 p. m., visit to Royal Electric company's lighting station and factory, then by special Grand Trunk train to the works of the Chambly Manufacturing company at Chambly.

A number of interesting and instructive papers upon timely subjects have been promised.

The proposed extensions of the Atlanta Consolidated Street Railway company this spring will aggregate $3\frac{1}{2}$ miles.

Litigation over Trolley Patents.

In the injunction proceedings instituted by the Thomson-Houston Electric company against the Union Railway company the United States Court of Appeals has reversed Judge Lacombe's decision, in which he granted an injunction pending final hearing in the case, involving the Van Depoele underrunning trolley patent No. 495,443, controlled by the General Electric company. The Union Railway company is using the Walker company's apparatus, and the officers of the latter company claim that under the decision the right to make and use the trailing freely mounted trolley arm pressed up against an overhead conductor is now no longer limited to the General Electric and Westinghouse companies and their licensees. Testimony is now being taken in this case, it is explained, and the court believed that the injunction should not be issued until the decision was filed, as it was expected that this would be done in a very short time.

This is but one of a number of patents under which the Thomson-Houston company is proceeding against users of trolleys. Among the other suits is one under Van Depoele's patent No. 424,381, the special feature of which is the use of a tension spring occupying a horizontal position and pressing the trolley arm upward. This construction is universally used, as it permits the trolley arm to be brought down close to the roof of the car. Another patent under which suit is pending is No. 502,243, which relates to the use of oppositely acting tension springs, of which one set "rests" while the other is in use.

Another patent of Van Depoele under which suit is pending is No. 495,383, which covers the reversible trolley, that is to say, one which may swing freely around its vertical axis so as to trail in either direction.

Two other cases will be argued under the present week, one on the Anderson patent No. 412,155 and the other under the Baker patent No. 437,961. These patents relate respectively to means for conducting current from the trolley wheel to the harp, and to the use of buffer-springs for checking the motion from the trolley arm when it escapes from the wire.

WAR NEWS.

[*Continued from page 227.*]

The Kerite company has received a large order for submarine cables from the government. The order, conditional on early shipment, is for 65 miles of cable of varying size. In order to fill the order at as early a date as possible the works will be required to run night and day for several weeks.

Elaborate preparations are being made at New Orleans in addition to those undertaken by the government. Several local defense committees have been organized to co-operate with the administration at Washington. The chief state and city engineers are upon the committee of engineers and surveyors, and all the branches of engineering are covered by committees of experienced men. The foremost electricians of the state are on the electric-service committee, and the chairman, E. L. Bemiss, offers 60 generators and three 135 horse power engines with the fullest equipment for instant use, besides men for operating searchlight and electric service plants.

Telephone "Leaks."—A curious story comes from Washington, to the effect that the use of the local telephone exchange presents an opportunity for "leaks." In consequence private lines have been established between the White House and the offices of Secretary Long, Secretary Alger and Assistant Secretary Day. The instruments will be placed on the desks of the president and his three advisers. A great deal of the business to be transacted must necessarily be of the most confidential nature, and without some such private means of communicating it will be necessary for the secretaries to make frequent calls on persons at the White House. This the officials have not only found tiresome, but it has subjected their calls to publicity and themselves to embarrassing inquiries. In the event of war it has been arranged to take charge of certain telegraph lines and place specially engaged operators in charge, who will handle all government messages. Two or three telegraphers are kept at the State Department all day and night to receive cablegrams directly from Madrid and Havana.

Electrical Men Offer Their Services.—Captain Eugene Griffin of the General Electric company, formerly of the army, has shown his patriotism by undertaking to organize an auxiliary corps of electricians to serve either in the army or navy in case of war. In doing this, says the New York Sun, Captain Griffin has the approval of the secretary of war and of Brigadier General John M. Wilson, U. S. A., chief of the Engineers' Corps. Several days ago Captain Griffin went to Washington to inquire of the chief of the Engineers' Corps if he had at his command a sufficient force of skilled electrical workers to prepare and plant submarine mines and torpedoes in case such work had to be done in haste. General Wilson replied that he had not, adding that there were then in the service only enough men to assign one man to about every 40 miles of the coast. Learning this, Captain Griffin offered to undertake the formation of an auxiliary corps, provid

ing the secretary of war would approve. This approval was readily obtained, and with it went the secretary's grateful acknowledgment of Captain Griffin's offer. Captain Griffin returned to New York and immediately went to work. He obtained a list of the most skillful workmen in the employ of his own company. By letter he informed each of them what he wanted and asked if they would volunteer for the service. In his correspondence Captain Griffin made it clear that in case of war the volunteers might be called upon to make needed repairs on warships after their service in the army was over. He also stated that in case the government had need of their services, they would draw their pay from the company during all the period of service, as well as pay from the government, with the privilege of going back to their old jobs when the war was over.

He then wrote to other electrical companies in New York telling them what he wanted to do and what he had done and asked them to co-operate with him. To electrical companies in Boston and Philadelphia he sent similar communications. The quickness with which the replies came was astonishing. From his own men Captain Griffin received the most loyal responses. Everybody to whom he wrote wanted to volunteer. The other electrical companies met the request in the spirit in which it had been made and promised not only co-operation, but many of them sent in the names of volunteers. Captain Griffin received favorable replies from the United States Electrical Supply company, from the Edison Electric company of Broooklyn, from the Mount Morris Electric Light company, from the Manhattan Electrical Supply company and from the Westinghouse company. From Boston came responses from the Edison Illuminating company, the Marlborough Electric Light company, from the Bell Telephone company and the Boston Telegraph company. A number of Philadelphia companies also responded.

The result was that in less than a week more than 1,000 men had been enrolled. Captain Griffin obtained the day and night address of every volunteer. These were sent to the office of the chief of the Engineers' Corps at Washington, where they are now on file. Some of the men have already been called upon for work in New York harbor and others will be at work in Boston and Philadelphia. A few have been sent to work in the harbors along the South Atlantic coast. It is thought that already enough have been enrolled to do all the emergency work that is needed. However, Captain Griffin is receiving additional names every day.

Frank W. Hawley has also offered to serve the government without pay at the head of a detachment of electricians.

Holland to Be Officially Tested.—The Navy Department has so far declined to purchase outright the Holland submarine torpedo boat, which is electrically operated. Acting on the advice of some of the experts, an official trial of the craft has been directed, and should it meet with the very rigid requirements laid down during Secretary Herbert's administration for this type of vessel the Navy Department will probably purchase the boat. Commander C. S. Sperry, formerly on duty in Washington as an ordnance officer, and now on duty at the New York navy yard, has been ordered to conduct the test.

Miscellaneous Notes.—According to a dispatch from Pittsburg, the Westinghouse Electric and Manufacturing company has begun to ship to the Brooklyn navy yard a lot of generators, motors, dynamos and wire to be used for the installation of electric power and lighting plants on board the merchantmen, old monitors and coasting steamers now being equipped by the government for service in case of war with Spain.

The Pennsylvania Electric company of Marietta has received a large order for telephones from the War Department, to be used for coast defense and signal stations along the Atlantic Coast. The company received instructions to rush the order.

What Electricity Has Done.

Dr. Elisha Gray has contributed several interesting articles to the Chicago Times Herald entitled "Elementary Talks on Science." The following is an abstract from a recent publication:

Electricity has given us a voice that can be heard a thousand miles, and not only heard, but recognized. It has given us a pen that will write our autograph in New York, although we are still in Chicago. It has given us the best light, both from an optical and a sanitary standpoint, that the world has ever seen. The old fashioned, jogging horse car has been supplanted by the electric trolley, and we no longer have our feelings harrowed with pity for the poor old steeds that pulled those human sardine boxes through the streets, with men and women packed in and hanging onto straps at the top of the car while everybody trod on every other body's toes at the bottom.

"In olden ti[illegible] a car
Drawn by a horse, it going far,
  And felt that we were blest;
Now the conductor takes the fare
And sticks a broomstick in the air
  And lightning does the rest.

"In other days, along the street,
A glimmering lantern led the feet,
  When on a midnight stroll;
But now we catch, when night is nigh,
A piece of lightning from the sky
  And stick it on a pole.

"Time was when one must hold his ear
Close to a whispering voice to hear,
  Like deaf men—nigh and nigher;
But now from town to town he talks
And puts his nose into a box
  And whispers through a wire."

So jogs the old world along. We sometimes think it is slow, but when we look back a few years and see what has been accomplished it seems to have had a marvelously rapid development. Something like 50 years ago a professor of physics in one of our colleges was giving his class a course in electricity. The electric telegraph was too little known at that time to cut much of a figure in the classroom, so the stock experiments were those made with the frictional electric machine and the Leyden jar. One day the professor had in one hour's time taken his class through a course of electricity, and at the end he said: "Gentlemen, you were born too late to witness the development of this great science." I often wonder if the good professor is ever allowed to part the veil that separates us from the great beyond and look down upon this busy world of ours in which electricity plays such an important part in our everyday life, and if so, what he thinks of that little speech he made to the boys fifty years or more ago.

Regulations for Patent Attorneys.

[Special correspondence of the Western Electrican.]

Washington, D. C., April 12.—For years the necessity for the establishment of a patent bar has been recognized. The laws governing the grant of patents are not as fully understood by the general public as they should be. The inventor, who for the first time seeks a patent, particularly if he resides at a distance from the larger cities, generally believes that all he needs in order to secure protection for his invention is a document issued by the Patent Office and bearing its seal. He does not know, apparently, that however valuable his invention may be, the patent issued therefor may, if not properly drawn, fail to protect him against infringers and be practically worthless and be no more in effect than a notice to all the world that the invention may be used by anyone without paying royalty to the inventor. Many such inventors, knowing of no patent solicitor in their neighborhood, trust their inventions to some pretended patent attorney, who, without the experience or qualifications necessary to render applicants for patent valuable service and without the high sense of obligation to the interests of his clients and with no purpose beyond securing fees from the inventors, spreads high-sounding, self-laudatory and utterly unprofessional advertisements broadcast over the country. Under the over-liberal rule of practice by which "any person of intelligence and good moral character may appear as the agent or attorney in fact of an applicant" not a few such attorneys have in the past been permitted to practice before the Patent Office, with the result that, on applications badly prepared and unskillfully and carelessly prosecuted, patents were issued which, while valid for all that they claimed, were worthless in that they failed to adequately protect inventions which, properly claimed, might have been worth thousands of dollars. Such practitioners, in not a few cases, have, through ignorance, inexcusable in those pretending to be competent attorneys, and in some cases through willful deceit, induced would be inventors to pay them fees for the preparation and prosecution of applications for devices which were upon their faces unpatentable and worthless. Such applications are of necessity rejected by the Patent Office, and the result has often been that the applicant not only loses the fees paid to the attorney, which are not inconsiderable, notwithstanding that such attorneys advertise to do their work cheaply and to prepare and prosecute the application for fees less than would fairly pay for conscentious and skillful work, but is sometimes led to believe the Patent Office untrustworthy and in league with unprincipled attorneys for the purpose of defrauding him.

In the interest of inventors and the public an earnest attempt to correct such abuses in the practice was made by the Patent Office during the past year. In consequence of disclosures of improper practices a rule was adopted requiring that all attorneys practicing before the Patent Office be registered. The rule went into effect on January 1, 1898, and has been generally accepted by practitioners.

National Electric Light Convention, Chicago, June 7th, 8th and 9th.

The most popular line from Cincinnati, Louisville and all points South to Chicago is the Big Four Route via Indianapolis; magnificent sleeping cars and unequaled dining car service. For maps, rates, etc., address E. O. McCormick, passenger traffic manager, Big Four Route, Cincinnati, O.

J. C. Morrison of Mora, Minn., has put in an electric plant for lighting his hotel.

CORRESPONDENCE.

New York Notes.

New York, April 11.—The great question, Will there be a war? forms the engrossing topic here with electrical men as well as with everybody else. As I write, the president's message to Congress is eagerly awaited, and everyone will be glad when the suspense is over. One effect of the war preparations of the government has been a demand for a large amount of electrical material, and much more will be needed. The management of the electrical exhibition to be held in Madison Square Garden next month announces that the exhibition will be given as announced, whatever the outcome of the difficulty between the United States and Spain.

Speaking of the electrical exhibition, it may be said that the outlook for the show is bright. The Brooklyn Polytechnic Institute and Dr. Samuel Sheldon, its professor of physics and electrical engineering, have loaned several interesting units and standards upon which precision in electrical measurements is based. Even the electrical public, while it hears a great deal of such standards, rarely sees them, and this exhibit therefore will be of technical and popular interest. The exhibit will include standards from the German Imperial Physico-technical Institute (Reichsantalt) whose celebrated work has been done under the guidance of such men as Helmholtz and Kohlrausch; and it is probable that these standards have never before been exhibited in public in this country.

The Rapid Transit Commission has decided that the Manhattan Elevated people must accept or reject the new franchises in their entirety. The company will not be allowed to pick out the profitable downtown franchises and reject the others; it must take all or none. The commissioners have adopted the detailed plans and specifications for the construction of the tunnel road, together with the form of contract. The commission will not advertise for bids for the construction of the tunnel until the contracts have been submitted for approval, as required by the act, to Corporation Counsel Whalen. The act, however, insists that the contract shall be returned by the corporation counsel within a reasonable time, and the commissioners are determined that their plans shall not be further obstructed by any undue dilatoriness on the part of Mr. Whalen.

Last week, after having a force working night and day for some time, the Metropolitan Street Railway company was enabled to run its first underground electric cars on Second avenue. Starting from One-hundred-and-twenty-ninth street, these cars run south along Second avenue to Stuyvesant street, through which street the line swings westward to Astor place. Some of the cars at the juncture of Fourth avenue and Astor place again turn southward and run to the Brooklyn bridge over the tracks of the Fourth avenue line, while others of the cars continue on to the terminus of the line, at Astor place and Broadway, where a transfer is given to the Broadway line.

The Sun makes the following interesting note: "At that busy corner, Grand street and the Bowery, there may be seen cars propelled by five different methods of propulsion—by steam, by cable, by underground trolley, by storage battery and by horses. Overhead, running up and down the Bowery, are the cars of the elevated railroad, drawn by steam locomotives. Running up and down the Bowery on the surface are the cars of the Third avenue railroad, drawn by cable. The Madison avenue cars, which turn into the Bowery at this point, coming along Grand street from the west, are run by the underground trolley system. The cars of the Second avenue railroad, which come up the Bowery and turn into Grand street going east, returning around the same corner going down, are still drawn by horses, as are also nearly all the cars of the Grand street crosstown line, which crosses the Bowery going east and west. But there are four cars now running on the crosstown line that are run by power from a storage battery."

It is stated that the Edison Electric Illuminating company of this city has purchased an acre and a half of ground fronting on the East River, where it is proposed to erect the largest electric-lighting station in the country. W. F. O.

Northwestern Notations.

Minneapolis, April 11.—The Twin City Rapid Transit company will change its Selby avenue cable in St. Paul to electric about June 1st. The company has let contracts for devices to overcome the heavy grade and expects to begin work changing the line about May 1st. The company will build a second interurban line between Minneapolis and St. Paul, and have it completed by July 1st.

A mass meeting at Henning, Minn., appointed a committee to secure estimates of cost for an electric-light plant.

A. D. Holliday, a village trustee at Two Harbors, Minn., has secured estimates of cost for an electric-light plant. It is probable that the village will take steps to put in a plant.

The city of Superior, Wis., is taking bids until April 30th for furnishing and installing a municipal electric-light plant.

Valley Junction, Ia., will probably take up the

matter of electric lights this season. The matter was favorably voted on a year ago.

C. W. McElyea of Ames, Ia., contemplates an electric line from Cedar Falls, Ia., to Des Moines. Arrangements are said to have been completed for its construction as far as Eldora.

The Lewiston Light company of Lewiston, Idaho, has contracted for a 200-kilowatt alternator. The plant is to be located on Asotin Creek, 10 miles above Lewiston, and will be run by water power.

The city of Algona, Ia., has voted for electric lights.

The survey for the proposed electric railway between Minneapolis and Anoka, Minn., shows a grade of but 18 inches to the mile on the east side of the river. The prospects for the construction of the road this spring are regarded as bright.

The Watertown, S. D., Water, Light and Power company contemplates putting in an electric light plant.

R. R. Dunn of St. Paul, who is interested in the Minnesota Point street railway in Duluth, Minn., says that in time the line will be changed to broad-gauge and electric power used.

A summons and amended complaint has been filed at Eau Claire, Wis., in the case of the National Electric Manufacturing company. The complaint alleges conspiracy, fraud and swindle. The plaintiffs are T. A. Harrigan and Morgan Brooks of Minneapolis, Fred Bonell and the Edward P. Allis company of Milwaukee, and the Eureka Tempered Copper company of North East, Pa. The defendants are the National Electric Manufacturing company, J. T. Barber, H. H. Hayden, Fitch Gilbert, R. E. Rust, G. T. Thompson, John S. Owen, D. R. Moon, A. J. Rust, T. F. Frawley, Bank of Eau Claire, Chippewa Valley Bank and Westville Lumber company. The case will be a warmly contested one.

Frazee, Minn., has completed arrangements with the Commonwealth Lumber company to furnish electric street lighting.

The street-railway company at West Superior, Wis., is preparing to change its tracks to standard gauge, so that cars can run through from Duluth without change. Thomas Lowry of Minneapolis, who is interested in the company, has been in the city looking the system over.

The mayor of Butte, Mont., vetoed the ordinance granting the street railway company a right-of-way for a line to Walkerville, a suburb. The council agreed with the company and passed it over the mayor's veto by an overwhelming vote.

A tramp stole 300 feet of insulated copper wire in Eau Claire, Wis., from the street railway and tied up the line for four hours. The man cut the wires after the power was off in the early morning and burned the insulation off by fire. The fellow was caught trying to dispose of it at a junk shop and arrested.

The Western Union Telegraph company has enjoined the county treasurer in Seattle, Wash., from levying on and attempting to seal its personal property to satisfy personal taxes for $174.68, and to accept in full payment of such taxes $52.18. The company was taxed on royalties and patent rights which it claims it does not own and, therefore, should not be taxed upon. C.

PERSONAL.

Charles A. Boyd, superintendent of the Walker company of Cleveland, has resigned his position. He will enter business for himself, doing general engineering, with offices in the American Trust building, Cleveland, O. Mr. Boyd has been with the Walker company for the last four years, starting as engineer in the railway-motor department, having charge of the design and construction. About one year later he was placed in charge of the entire engineering department, and was promoted to the position of assistant superintendent on January 1, 1897. The following March he was appointed superintendent of the Cleveland works, having in charge both the engineering department and shops.

ELECTRIC LIGHTING.

James C. Fredlock of Piedmont, W. Va., has received contract from the city for electric lights and will establish a plant.

Sealed proposals will be received at the office of the city clerk of Natchez, Miss., until Thursday, June 2d, at 4 p. m. for lighting the streets, alleys, parks and public buildings of the city with electricity for a term of 10 years, from March 1, 1899, in accordance with plans and specifications on file in the clerk's office. The mayor and aldermen reserve the right to reject all bids. Specifications will be furnished those wishing to bid, upon application to the city clerk, Thomas R. Quarteram.

ELECTRIC RAILWAYS.

It is stated that the Cumberland (Md.) Electric Railroad company has decided to build an extension four miles long into the suburbs.

The Collins Park and Belt Railroad company of Atlanta will probably extend its line to Marietta, Ga., within the next few months. The plan is to build an extension of from 14 to 19 miles.

Crage & Tench of Buffalo have secured the contract for building the Lima and Honeoye Falls electric railroad. The contract also includes the wiring of the streets of both villages for electric lights, and the construction of the power house.

During the month of March the Metropolitan Elevated West Side Railway company of Chicago (electrically operated) carried a daily average of 68,597 passengers—the largest in its history. The receiver has now cash on hand amounting to $270,000.

A committee of the City Council of Chicago is considering a new street-car fender ordinance. This ordinance proposes to remedy the legal defects of the present ordinance by specifying that the fenders shall be of the steel-basket style. The ordinance gives the railways until June 1st next to equip all cars.

Mayor Harrison of Chicago has vetoed the ordinance passed by the City Council granting the Chicago, Milwaukee and St. Paul Railroad company permission to substitute electricity for steam upon its Evanston branch. The mayor objected that the compensation was inadequate, the term of the franchise (20 years) too long and the restrictions not sufficiently explicit. The veto was sustained.

ELECTRICAL SECURITIES.

The United Electric Securities company has declared a semi-annual dividend of $3.50 on the preferred stock, payable May 2d to stockholders of record April 20th. The last dividend declared was in February, 1896.

The Massachusetts railroad commissioners have authorized the Norton and Attleboro Street Railway company to issue $40,000 20-year five per cent. mortgage bonds, $22,000 of which are to be applied to the roadbed and rolling stock and $18,000 to electrical equipment.

For the month of March the earnings of the Brooklyn Rapid Transit company's system increased $58,627.31 over the same period of 1897 and $79,693.90 over 1896. For nine months ended March 31st the gain has been $176,453.47 over the same period of the previous year. For March, 1898, the total earnings were $466,387.66, and for the nine months $4,073,770.93.

The March earnings of the Brooklyn Elevated Railroad, compared with last year, show a decrease of $17,427, the road having earned only $132,856 against $150,283. The earnings reflect the diminution in traffic caused by the operation of trolley cars across the bridge. It is estimated that the Kings County Elevated earnings, which have not yet been made public, will show a loss of about $10,000.

MISCELLANEOUS.

It is stated that the employment of large electric overhead traveling cranes in locomotive shops is superseding the use of transfer tables. Several cranes of this description having each the capacity of lifting a complete locomotive are now in operation.

The United States Treasury Department is inviting sealed proposals until April 19th for installing an electric-light and power plant in the United States courthouse and postoffice building at Pittsburg. Specifications and plans can be obtained upon application to the secretary of the treasury, Washington, D. C.

A Sheffield correspondent of the English Hardware Trade Journal commends the promptness with which American manufacturers ship goods for the export trade. He tells of an English customer who cabled for 60 electrical specialties required for certain railways. These were promised in 14 days. "I should like to know," the buyer said, "where in this country I should get such smart attention." "Remember," he adds, "these electric goods thus hurriedly cabled for are not in stock; all have to be made." The correspondent is afraid that a good deal of trade which ought to be done in England is lost from such causes as this.

TRADE NEWS.

The Bullock Electric Manufacturing company will soon issue a bulletin on "Motors for Machine Tools and other Machinery."

The Westinghouse Electric and Manufacturing company has just opened a new branch office at Austin, Texas. Mr. J. E. Johnson will have charge of the office and of the further extension of Westinghouse business in the Southwest. The large contracts which this company has been handling in Mexico and the Texas region have led to the establishment of this new center of electrical trade.

Easter cards are not generally exchanged among commercial acquaintances, but the American Electrical Works has sent out a very pretty memento in the form of a representation of an egg-plant and a package of seed, with the injunction to plant the seed and raise a commemorative egg plant, at the same time expressing the hope that "its growth and fruit may frequently bring to mind" the American Electrical Works.

Moser & Wilson report that business with them is very good, and although they are putting on more help they cannot catch up with their orders. They have doubled their foundry capacity and are working a full force. They closed a contract April 4th with the Sprocket Brake company for 5,000 sprocket brakes to be used on bicycles, which will keep them busy for some time. The brass jobbing business is good and they say they are well satisfied with their prospects for the summer.

The electrical trade will be interested to know that a new electrical firm has opened offices in the Marquette building, Chicago. The new institution starts business under the name of Harding & Hammer. Both partners are already well known to the western trade. Mr. Harding has done business under his own name for years in the Marquette building, handling dynamos and electrical machinery of a general character. Mr. Hammer until some months ago was a partner in the firm of Cutler & Hammer. It may be stated incidentally that the new combination seems a most excellent one.

Eugene Munsell & Co. of New York and Chicago are enjoying an excellent trade on their India and amber mica segments for railway motors. Several heavy orders have recently been received, one of which was probably the largest ever taken for mica segments from an electric railway. It consisted of more than 800 pounds of the India and amber segments. The firm carries a large stock of mica, both in the sheet and cut to size, and has unequaled facilities, both at New York and Chicago, for executing orders promptly. It will take pleasure in sending samples for trial to any electrical manufacturer, repair concern or street railway that may request them.

A neat folder giving a complete list of all the vessels in the navies of the United States and Spain and showing classification, speed, number of guns, etc., has just been issued by the New York, Ontario and Western Railway company through the western passenger agent, E. T. Monett. The relative strength of the two navies can be seen at a glance, and an intelligent comparison made. Anyone can obtain one of these folders without charge by application to E. T. Monett, 120 Kinzie street, Chicago. The New York, Ontario and Western railway in connection with the Wabash railroad is the only line running through free reclining chairs between Chicago and New York.

The increasing application of storage batteries to electric-light and railway-station use, as well as to street cars, motor carriages, electric launches, etc., where a portable source of power is requisite, has led the General Electric company to develop a special type of meter which will show at a glance the amount of energy available in the battery. The Thomson recording storage-battery meter resembles in general appearance the standard Thomson recording wattmeter, and is, in fact, a development from it, the mechanism being almost exactly similar. The accuracy and durability characteristic of the standard type have both been maintained, while additional precaution is provided against injury from shock or vibration. The meter is provided with a single indicating needle moving over a horizontal semicircular dial.

C. W. Bartlett of Des Moines, Ia., has severed his connection with the Mutual Telephone company of that place to accept a position with the Keystone Telephone company of Pittsburg, Pa., as western agent with headquarters at Des Moines. Mr. Bartlett has made an enviable reputation for himself in building up the Des Moines plant to the high position it occupies to-day as one of the best independent exchanges in the country, and the practical knowledge thus obtained makes him well fitted to give expert information on telephone construction, what to use, and how to use it. Adding to this the high class of apparatus he will have in representing the Keystone Telephone company, he will occupy a position that will be of great advantage to exchanges in that section. The combination is a happy one.

A. L. Ide & Sons of Springfield announce the granting of a patent, dated April 5th, on a "combined shaft and disk." This refers to the well-known construction of the improved crank-shaft now used in the Ideal engines, consisting of shaft and disk of one piece of gun metal or one integral casting, with steel core or strengthening rod cast in the center of the shaft and made a part thereof. This construction has been used by Ide & Son for several years past, and owing to the great strength of this patented construction, out of several thousand engines equipped with these shafts, not one has failed to withstand the greatest strain of the most exacting service. The makers have found that the gun-metal makes a more serviceable, better wearing and more perfect bearing than a shaft where the steel comes in contact with the babbitt of the bearing.

The Davis & Egan Machine Tool company of Cincinnati will in the future be known as the American Tool Works company. The change of name goes with a reorganization of the concern, which includes an increase of the capital stock from $500,000 to $1,000,000. The steadily increasing foreign business of the company has necessitated its enlargement, and the change of name is made in the interest of this same foreign business. Mr. Charles Davis will be continued as president of the Ameri

can Tool Works company. The same line of manufacture, of tools for use in the manufacture of all kinds of tools used in the manufacture of machines and all metal work, will be pursued. The product of the concern is now said to be sold three months ahead. Mr. Davis, the president, will leave for Europe in two or three weeks, as soon as the reorganization is completed, to spend the summer on business.

Kohler Brothers will represent the Northern Electrical Manufacturing company of Madison hereafter as sales agents, with headquarters in Chicago. Their territory includes Illinois, Iowa, Missouri, Indiana, Nebraska, Kansas, Kentucky, Tennessee, Michigan, Ohio, Pennsylvania, New Jersey, Maryland, Delaware and District of Columbia. It may be said that not only in Chicago but throughout the territory in which this enterprising firm has operated it is recognized for ability and perseverance. There are few concerns in the country of this class that have a record for sales equal to that of Kohler Brothers. The Northern company has been making some improvements in its product as well as its factory, and it is now prepared to furnish a complete line of stationary motors for all classes of work. Its facilities for machines of which special requirements are demanded are unexcelled. A line of the company's motors will be exhibited at Kohler Brothers' offices in the Monadnock building.

BUSINESS.

The Buckeye Electric company is putting out a handsome catalogue of its special coiled-filament lamps. Consumers in western territory will be supplied on application to J. H. Cooke, 753 Monadnock building, Chicago.

The Cincinnati Screw and Tap company sends out a number of circulars, stitched together, to illustrate the variety of its goods. All kinds of bolts, screws and nuts for machines are shown and also machinists' tools. A complete catalogue is sent on application.

A neat booklet shows the electrical heating devices made by the American Electrical Heater company of Detroit. The electric soldering irons, laundry irons, tailors' irons, curling-iron heaters, heating disks and portable air heaters made by this company are guaranteed.

The Card Electric company of Mansfield, O., says that business never was better, and that it has been found necessary to run the shops at night. Important extensions to the factory have just been completed, and the company is looking forward to further additions in the early summer.

Huebel & Manger, Brooklyn, are receiving many orders for their style "F" skeleton bell. This bell is made in sizes ranging from three inches to 15 and is a most satisfactory signal and fire-alarm bell. For use in mines, factories, schools, hotels, etc., and on railroads it is especially recommended.

The Walker company announces a "converted type" of belted generator which is said to conform very closely in design and excellence to its direct-connected dynamos. A recent circular gives a description of this type, with illustrations.

A ventilating fan can be driven by a water motor as well as by an electric motor. The Schneider Manufacturing company of Cleveland says that water-driven fans are a success, laying stress on the low cost of maintenance; and it will send a circular describing its Gem and Globe motors on request.

The Pennsylvania Railroad company has ordered for its Altoona shops two 160 horse power tandem compound engines, arranged for direct-connection to 100-kilowatt dynamos. The engine was furnished by the Ball Engine company, Erie, Pa., and dynamos by the General Electric company. The city of Crowley, La., is installing an electric-light plant. Ball engines furnish the power. The city of Scranton, Miss., is installing a 75 horse power Ball engine, to be direct-connected to General Electric dynamos.

Mathias Klein & Son of 87 and 89 West Van Buren street, Chicago, are now issuing their catalogue No. 3, of linemen's construction tools, which they would like to see in the hands of everyone interested in line construction and maintenance. They will send the catalogue to anyone who will furnish his address. The firm is one of the oldest manufacturers of linemen's tools in the West, and its aim is to issue only first-class goods and at a price consistent with good quality. It is experiencing an active demand for climbers' splicing clamps, wire clamps and construction tools generally.

Descriptive catalogue No. 32 of the Holtzer-Cabot Electric company of Boston, Mass., is devoted to the company's new type of magneto bells and to its various telephone apparatus, which is claimed to be more extensive than that manufactured by any other concern in the country. The company's long experience of nearly 25 years places it in a position to know all about the necessities of the trade. This catalogue seems to cover everything that is needed in a telephone exchange, going minutely into detail of the various articles that would be called for by purchasers of telephone goods

Users of miniature incandescent lamps will very readily appreciate the advantage of having a miniature lamp of a standard reliable make that can be depended upon for efficiency and length of life. The Packard 3gn lamp, which is a miniature lamp about two inches long over all and one inch in diameter, fills the demand for a high-grade miniature lamp. It is mounted with regular Edison candelabra base, gives about two candle power and burns four in series on 50 to 60 volts, or eight in series on 100 to 120 volts. This lamp is carried in stock in Chicago in large quantities by the Electric Appliance company, which always holds itself in readiness to ship promptly any number of these lamps and the necessary sockets.

Walker, Bailey & Co., of Buenos Ayres, Argentin Republic, are now installing the first outfit of electric motors for supplying all of the motive power in a factory that has ever been installed in that country. The plant is for a weaving factory, and it is to be driven by Lundell electric motors of such power that each motor will drive six machines. The Lundell motor seems to be gaining rapid recognition among large power users, owing to the fact, it is stated, that it has never lost in competition with other motors at the hands of engineers, and the further fact that it has given invariable satisfaction during all the years it has been upon the market. One of the latest contracts awarded the Sprague company is that from the John Stephenson Car company of Elizabethport, N. J. Each of the Stephenson machines will have its independent Lundell motor, and the sizes used will be from three to 40 horse power, mostly large-size machines. Some of them will be direct-connected and some geared. In addition to the power motors, the Sprague company has secured a contract for exhaust fan outfits. The plant will be one of the largest of its kind in the country, and will employ only Lundell motors.

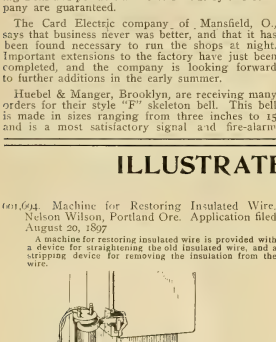
The Armington & Sims company of Providence, R. I., manufacturer of the Armington & Sims engine, reports that it is receiving a large number of orders and that the prospects for a continued trade are bright. The company recently took an order from the Quidnick Manufacturing company of Quidnick, R. I., for a 400 horse power slow-speed new type cross-compound engine. This will be the first of its kind built at these works, and is creating some little comment in engineering circles, owing to a number of changes in its construction. Among other orders recently taken was one for two engines to be delivered to the government for operating searchlights, to be delivered within five days; one for a 75 horse power high-speed engine for Mount Hope Fire, Providence, R. I., and an engine for the Wickford Woolen company. The placing of the order for the University Club of New York city, for an engine to be placed in its club house, was awarded to the Armington & Sims company after close investigation into the merits of the various engines offered for sale. One of the supprises the company has experienced in the way of new business is the receipt of an order for two small engines to be shipped to the Klondike. It is pleasant to note the success which has attended the efforts of General Manager Fred. M. Bushnell to place this well-known concern in its former position. Mr. Bushnell is now arranging a number of important changes to increase the capacity of the factory.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued April 5, 1898.

601,694. Machine for Restoring Insulated Wire. Nelson Wilson, Portland Ore. Application filed August 20, 1897

A machine for restoring insulated wire is provided with a device for straightening the old insulated wire, and a stripping device for removing the insulation from the wire.



NO. 601,805.

601,717. Solenoid Blow-out for Dispersing Arcs Formed in Breaking Electric Circuits. Sidney H. Short, Cleveland, Ohio. Application filed November 1, 1897

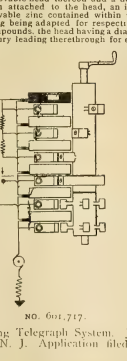
Separable contacts are arranged in an electric circuit with a spiral conducting coil arranged in proximity to the contacts, and a magnetic field circuit therewith, the coil being adapted to be included in the circuit of the contacts at the moment circuit is broken between the contacts.

601,730. Heat Detector for Electric Fire-alarm Systems. John D. Gould, Brooklyn, N. Y. Application filed January 30, 1896.

Included in this device are combined an insulated block a recess or chamber in the block, a bulb or globule or knob of fusible metal or compound of metal suspended over the recess, and two wires or conductors extending into the chamber independent of and insulated from each other, two other wires arranged in close proximity side by side but electrically separated from each other, one of the wires being formed of a metal fusible at a low temperature, the latter wires at one end being respectively connected to the wires of the block and respectively connected at their other ends to the poles of an electric battery.

601,758. Electric Lantern. Oscar C. Prasse, West New Brighton, N. Y. Application filed June 28, 1897.

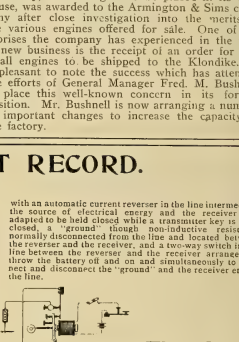
The special feature is a battery comprising a casing having a removable head thereon and a depending cylindrical carbon attached to the head, an inclosed porous cup and a movable zinc contained within the cup, the cup and the casing being adapted for respectively containing chemical compounds, the head having a diagonal vent containing mercury leading therethrough for escape of gases.



NO. 601,717.

601,768. Printing Telegraph System. John Burry, Fort Lee, N. J. Application filed September 10, 1897.

A receiver is provided with printing and polarized type-controlling electro-magnets operated by the line current, with an automatic current reverser in the line intermediate the source of electrical energy and the receiver and adapted to be held closed while a transmitter key is held closed, a "ground" though non-inductive resistance normally disconnected from the line and located between the reverser and the receiver, and a two-way switch in the line between the reverser and the receiver arranged to throw the battery off and on and simultaneously to connect and disconnect the "ground" and the receiver end of the line.



NO. 601,768

601,805. Telephone. Thomas F. Ahearn, Detroit, Mich. Application filed April 20, 1897.

A transmitter is suspended on a horizontal axis in a plane in or parallel to the diaphragm, so journaled that the speaking tube is normally downward, with means connecting the movable receiver hook with the transmitter, coupelling the latter to rotate so that the diaphragm is in substantially a perpendicular plane when the receiver is detached from the hook.

601,871. Electro-magnetic Circuit Breaker. Gano S. Dunn, East Orange, N. J. Application filed June 12, 1897.

A resistance controlling switch is employed to govern means for locking the circuit breaker against closure in certain positions of the switch and means for permitting the opening of the circuit breaker in all positions of the switch.

601,902. Electric Brake Mechanism. Alexis Van derbeck, Scammon, Kan. Application filed September 13, 1897.

A device is described having fixed electro magnets and a movable plunger operating axially through one electro-magnet, with its extremities permanently connected and the ends thereof, for attraction by the other, and adapted to be operatively connected with brake mechanism.

Western Electrician.

EVERY SATURDAY.

Vol. XXII. CHICAGO, APRIL 23, 1898. No. 17

Electricity at the Omaha Exposition.

Preparations for the formal opening of the Trans-Mississippi and International Exposition at Omaha on June 1st are rapidly nearing completion. The buildings have been erected and the work of improving and beautifying the grounds is already well advanced, leaving scarcely anything to be done save the ornamentation of the buildings and the reception and arrangement of exhibits. During the next few weeks this work will be pushed as expeditiously as possible, so that on the day set for opening the gates to the public the entire scene will have undergone a complete transformation and the spectacle presented will be one of surpassing beauty.

As its name implies, the exposition will be essentially representative of the trans-Mississippi region, and it is intended to fully illustrate the wealth-producing power and the extent of productive industries of the Great West, but the scope of the enterprise has expanded far beyond the limits of the original project, the national government and 35 states having recognized the importance of the event by actively participating in it and contributing towards its material success. Moreover, by direction of President McKinley the State Department extended invitations to rulers of foreign nations to participate, and these official invitations were supplemented by formal invitations transmitted by the president of the exposition company to the governments of all nations with which the United States maintains diplomatic relations. Many favorable responses have been received. The Canadian exhibit will be in all respects worthy of the Dominion government. The Central and South American states will furnish evidence of the material and industrial progress attained by those nations. Lord Salisbury, prime minister of England, has officially notified the secretary of the treasury that the British government is affording assistance to exhibitors and encouraging a representative display. The Chinese government has informed the authorities at Washington that it will be represented. President Diaz of Mexico has shown a personal interest in the affair. Mexico will send a characteristic exhibit, and he himself will send his renowned band. The government of Venezuela has formally accepted the invitation, and Costa Rica and Bolivia will send official representatives and join in making exhibits of the industries and products of their respective countries. So much for the international scope of the exposition.

The artistic features are equally well assured. The location of the grounds is admirably suited for the purpose, commanding a magnificent view of the river and being easily accessible and conveniently situated with reference to the business portion and residence part of the city. What is locally known as the Kountze tract, which is 670 feet wide and is defined by Sherman avenue on the east and Twenty-fourth street on the west, was selected for the focus of the group of main buildings. This ground is nearly half a mile long, and in the center there is a canal extending the greater part of the distance. This basin is 150 feet wide at the east end, and at the west end it runs into a trefoil or three-lobed lake 400 feet across. On the east is an area of 60 acres stretching along the bluffs and overlooking the river and country beyond. The remainder of the exposition ground lies north of Kountze tract, west of Sherman avenue, and includes the old fair ground, and the land beyond it, embracing in all about 80 acres.

The main architectural feature is bound to be the Grand Canal Court, and they will at once remind visitors of the magnificent Court of Honor at the World's Fair. The main buildings are ranged along either side of the basin. At the west end stands the Government building, flanked by imposing colonnades which converge toward the west. The Arch of States forms the main entrance on the south line at Twentieth street. Entering this arch the visitor arrives at the Court of the Grand Canal, opposite the Administration Arch, the Palace of Agriculture being on the west and the Manufactures building on the east. The canal or basin is spanned occasionally by picturesque bridges, built with little arches to permit the passage of gondolas and electric launches. Its two ends terminate respectively at the Government building on the west and at the viaduct on the east.

Although the grounds and buildings will be attractive by day, the real beauty and grandeur of the conception can only be appreciated at night when with the aid of electric lights the scene presented will rival a picture of fairyland. Every building will be outlined with incandescent lamps—cornice, window, pillar, dome and water-edge. The salient points of the Government building architecture will be made distinct by electric starpoints. On either side will be defined the colonnades which connect the sister buildings by pillars of light. To the left the Fine Arts building will rivet the attention with domes light-encircled, cornices ablaze, pillars and pilasters illuminated. On the opposite side of the lagoon is the classical Agricultural building. It presents a brilliant opportunity for incandescent decoration. The upper lines, including the balustrades, and the imposing entrance and corner towers, will stand revealed by the numerous electric punctuation points. The Administration Arch will raise its lofty spire outlined in symmetrical lines of light to the uppermost point. The Manufactures building will have the prominent roof cornices, caps of columns, pedestals and other points of vantage embla zoned with incandescent lights, and the Arch of States will be girdled with bands of light, while the Liberal Arts building will be vividly outlined along its cornices. The Mines and Mining building is especially adapted for this beautiful decoration, and right royally has it been bedizened and crowned

FIG. 1 ELECTRICITY AT THE OMAHA EXPOSITION.—VIEW OF MACHINERY AND ELECTRICITY BUILDING FROM THE WEST

its graceful portico clearly defined, the towers wearing scintillating crowns and the windows shining brightly. Facing this structure is the palace of Machinery and Electricity, with all effective points penciled in light. The east end of the lagoon, in front of the last two mentioned buildings, in company with the adjacent terraces, landings and broad viaduct leading away from it, will be brilliantly lighted by incandescent lamps supported by fanciful standards of special design.

Several special features have been designed. Surmounting the Government building is the heroic figure of Liberty Enlightening the World, holding

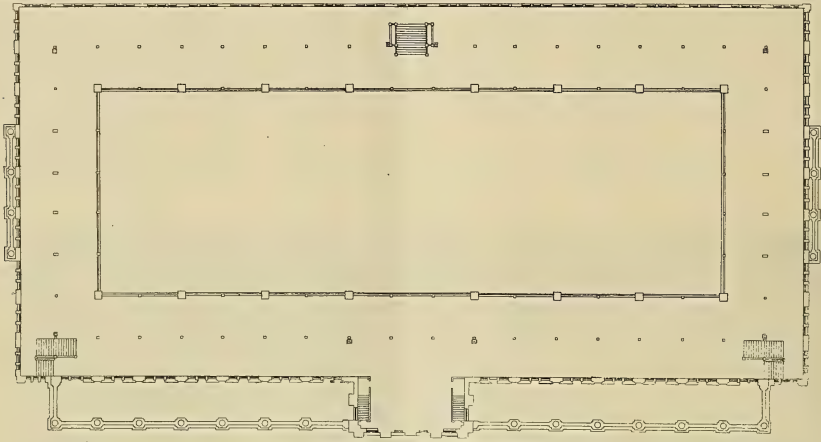


Fig. 2 Plan of Gallery of Machinery and Electricity Building.

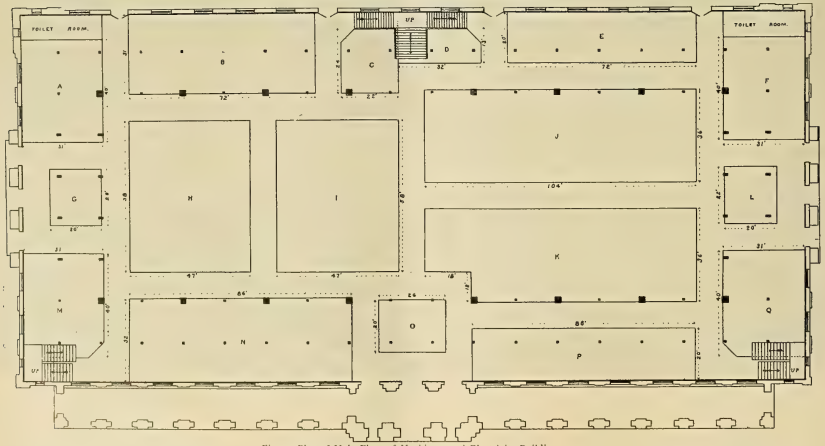

Fig. 3. Plan of Main Floor of Machinery and Electricity Building.

ELECTRICITY AT THE OMAHA EXPOSITION.

tilus" will be bombarded from an invisible source with light ever-changing in color and of great intensity, enshrined in luminous floating lilies. Mr. Stieringer designed the lighting effects, and those who have examined his plans and followed the progress of the work declare that this will be the most striking feature of the exhibition.

The commanding position of electricity and the popular interest in this department has been recognized by the management in devoting one of the main buildings conjointly to machinery and electricity. An excellent picture, reproduced from a recent photograph of the building, is presented in

corners. A high central court 248 feet long by 80 feet wide is lighted from the skylights and clerestory windows above the roof.

The character of the exhibits sheltered by this building will be shown by the decoration, which has not yet been completed. The ornamental spandrels and panels will receive all of their motifs and suggestions from machinery. In the plans the cresting at the top is composed of cogwheels, this principle being carried out in all of the decorations. The underlying principle and function of machinery is symbolized by the groups of statuary on the top of the building. At each of the four corners are

a powerful searchlight aloft. Liberty's body is to be jeweled with incandescent lamps; about her head there will be a scintillating tiara, and the upheld torch encircled with lamps. Beneath the figure several lines of light will completely girdle the cupola above the dome. Streamers of light will cover the dome, apparently held to their places by five-pointed stars on either side of the dormer windows, and below these another line of light will completely surround the base of the dome. Arising from the roof of the central portion of the building a series of flambeaux supported on shafts of artistic design will cast their radiance on surrounding objects. The allegorical figures on the upper cornices and flanking the dome will be outlined harmoniously and effectively. Clusters of lights border the Mirror, and in the center of this charming scene the electric fountain "Nau

Fig. 1. The diagrams show the floor plans for the gallery (Fig. 2) and the main floor (Fig. 3). This building is located in the northeast corner of the grand court, being east of the Manufactures building and across the lagoon from the Mines building. It has a frontage of 304 feet and is 144 feet deep. There are triple entrances on the main-floor level in the center of the main front and similar groups in the centers of the east and west fronts, with four emergency exits in the north wall. In front of the building, flanking both sides of the main entrance, is an open portico 16 feet wide, running the entire front of the building. Above the main floor is a gallery 32 feet in width, extending around the four outer walls. The gallery is reached by spacious staircases located at convenient points in the building. Commodious toilet rooms are provided in the rear

groups representing the early supremacy of man over the untamed forces of nature. These forces are represented by wild animals. Men in their youth are seen subduing them for the simple purpose of escaping injury and the preservation of their own lives at the sacrifice of the natural forces. A higher supremacy is shown by the center group, which is the dominating feature of the entire design. In this, man, developed beyond the youthful stage, having wisdom, takes these untamed, unharnessed forces of nature, and harnesses them to his chariot, making them do his bidding, symbolizing in a direct way the service which machinery does for man in using the powers of steam, electricity and gravity.

Color enters into the design with maximum importance. The ornaments in the panels under the

porticos and over the main entrances will be highly emphasized by small background spaces of strong colors. The entire building will be a series of yellow and ivory tones, growing more intense as they reach the top, culminating in the dull golden stationary which surmounts the building and symbolizes its use. The building was designed by Dwight H. Perkins of Chicago.

Among the electrical features that will be shown in this building will be the latest developments in power transmission, a working telephone exchange, a miniature central-station plant and personal exhibits by Edison, Tesla and Thomson. Prof. R. B. Owens is at the head of the Department of Electricity.

Coupling Switches for Accumulators.

Dr. Ch. Truchot of the Clermont-Ferrand University recently contributed an article to the Archives d'Electricité Médicale, in which he described

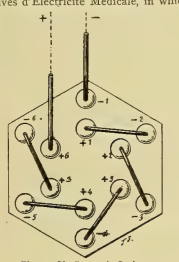

Fig. 1. Six Groups in Series.

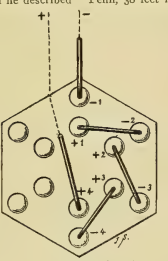

Fig. 2. Four Groups in Series. Two Groups Idle.

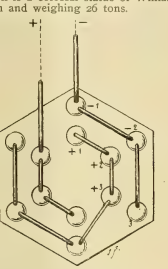

Fig. 3. Three Groups in Parallel. Two Groups in Series.

COUPLING SWITCHES FOR ACCUMULATORS.

a new combination of switches to control the output of a battery, changing at will the quantity and tension of the current discharged. For his own convenience the doctor had installed a storage-battery plant which he used in electrolytic and cautery work, for lighting, and for driving motors for static machines. Current for charging was taken from a dynamo delivering 10 amperes at 55 volts.

The battery comprised 30 elements of 70 ampere-hours, discharging normally 12 amperes. The elements were arranged in six groups, each comprising five accumulators, connected by soldered contacts. To effect the changes and combinations desired, the doctor made a block of insulating material, hexagonal in shape, with 12 cavities arranged as shown in Fig. 1. The six positive wires were brought to the six interior contacts, and the six negatives were brought to the outer cavities. These cavities were filled with mercury, and a connecting bridge of copper wire placed across two of these terminals connected them. To group all of the elements it was only necessary to place them as shown in Fig. 1, —1 being one pole of the combination and +6 the other pole. If it is desired to connect up 20 elements only, the arrangement shown in Fig. 2 will accomplish this, leaving one-third of the battery idle. Fig. 3 shows a more complicated arrangement, namely, three groups in quantity and two groups in tension. It will be readily understood from an examination of these three figures that many combinations of quantity and tension may be secured with a large battery plant, and any chosen number may be discharging while the remainder are being charged.

"Curious Things Electrical."

Frank L. Perry, the assistant business manager of the Western Electrician, delivered an illustrated lecture on "Curious Things Electrical" at the Kenwood Evangelical Church on the evening of April 14th for the benefit of a West Side church. Mr. Perry's lecture was a popular exposition of the applications of electricity. He performed several interesting experiments, displayed a large number of stereopticon views and read letters from Elihu Thomson, Graham Bell and Tesla, detailing the most curious electrical experience of each of these gentlemen. Mr. Perry's lecture showed exhaustive preparation, and he was heartily applauded. In particular, his graphical explanation, in colors, of the principle of the rotary magnetic field of the Tesla motor deserved praise for ingenuity and effectiveness

Introspection.

(From the London Electrician.)

Our great fault, as a nation, is excess of conservatism; and the incubus of numerous and important vested interests conspires with that fault to throw obstacles in the way of radical changes in our industrial methods. Our engineering manufacturers are, however, awakening to the fact that such changes are imperative; and, whether by the importation of American labor-saving apparatus and American ideas, or by rousing ourselves into activity to devise such apparatus for ourselves, the retention of that supremacy in engineering industry which Great Britain has hitherto held can only be insured by falling into line with the new order of affairs, and adapting ourselves more perfectly to a palpable change in our commercial environment.

A Big Job of Electroplating.

In a recent paper read before the Engineers' Club of Philadelphia by Mr. Francis Schumann on "The Metal Dome of the City Hall Tower, Philadelphia, Pa.," there is an interesting description of the process of electroplating 120,000 square feet of surface of the cast-iron shell of that dome. The tower is 548 feet in height and weighs over 60,000 tons. It is built of masonry for a distance of 337 feet from the ground; above this shaft is the dome which Mr. Schumann describes. The crowning feature of the work is a colossal statue of William Penn, 38 feet high and weighing 26 tons.

The portion of the paper relating to the electroplating of the shell of the dome is as follows:

The electroplating of the shell of the tower was performed in a building especially erected for that purpose. It was 60 feet wide by 120 feet long, of heavy framework of wood, one story high, sides and roof covered with corrugated iron. A row of timber posts, supporting the middle of the roof trusses, divided the floor area into two clear spaces. The north space contained two rows of pits, three in each row, made water-tight by concrete and cement sides and bottoms. The pits were of dimensions to receive the plating tanks, and of such depths that the rims of the tanks were about 18 inches above the floor level, and of sufficient width and length to leave a space of eight inches between the outside of the tanks and walls of pits. This space was kept full of water to a level with the surface of the liquid in the tank, and thus acted as a counterpoise to prevent both the bulging of the sides of the tanks as well as to prevent leakage, the hydrostatic pressure being the same on both inside and outside of the tanks.

Over the center of each row of pits, and attached to the under side of the roof trusses, was a track made of 10 one-half-inch rolled beams, carrying three trolleys and chain-hoists, each of sufficient capacity to raise three tons. The trolleys were moved back and forth on the tracks by means of a system of ropes running over sheaves and leading to geared drums operated by hand cranks.

The tracks, which extended beyond the tanks, permitted the transportation of a piece to be plated, by means of the trolleys, from place to place, as might be required, the raising and lowering being done with the chain-hoists.

At the end of the rows of tanks was located the cleaning floor, having a small tank supplied with running water.

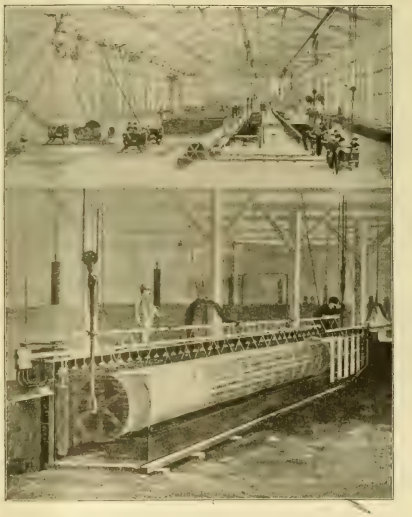
The other or south space of the floor was occupied in part by a 75 horse power boiler and 50 horse power steam engine, four dynamos, storage room and work benches for marking, inspecting and assembling the piece for shipment.

The first row of plating tanks were:

1. Caustic-soda tank, of plate-iron, five feet wide, five feet deep, and 31 feet long. The temperature of the solution was maintained at about 210° F. In this the articles were immersed from two to six hours, for the purpose of removing all grease or fatty substance. From this tank the piece was taken to the

2. Pickling tank, made of wood, same dimensions as last, lead lined, and containing a 10 per cent. solution of sulphuric acid, at a temperature of about 150°, the article being immersed from two to six hours to loosen or remove all rust, silica or other matter, the cleaning being by scraping and rubbing with wire brushes, which was done at the cleaning floor, previous to treatment in the

3. Alkali-copper tank, also of wood, and of same dimensions as the last. This bath was about 150° temperature, and was the first in which a deposit of copper or alloy of copper and tin was applied. The anodes were hung to 1¼-inch diameter brass conductor rods, supported on short brackets at both sides of the tank, while the cathode, or piece to be plated, was hung to a single two-inch diameter brass conductor rod, suspended over the middle of the tank by means of ropes over sheaves overhead balanced with counter weights. The round conductor rods were connected to flat copper conductors from the dynamos by flexible copper wire strands, to permit shifting of the round rods. The time of plating was about 24 hours, under four volts and from 1,000 to to 2,000 amperes.



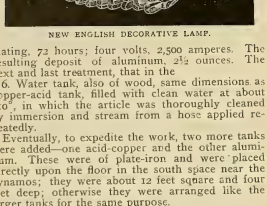
A BIG JOB OF ELECTROPLATING. VIEW OF PLANT, SHOWING A 1000-POUND COLUMN IN THE BATH.

From this tank the piece was taken to the second row of tanks, the first being the

4. Acid-copper tank, similar in all respects to the last, except that it was lead-lined and not heated, and that the conductor rods were respectively two

and 2½ inches in diameter. At one end of the tank, in a corner, an agitator for effecting circulation of the liquid was located, consisting of an upright copper tube about eight inches diameter, within which a small propeller wheel secured to a vertical spindle revolved, driven from the line of shafting. The anodes were of copper, and time of plating 72 hours, depositing about 14 ounces of copper to a square foot of surface. The voltage was four and amperage from 1,000 to 2,000. The next was

5. Aluminum tank, of wood, five feet wide, eight feet deep, and 31 feet long. This bath was heated to about 180° by means of steam-pipe coils lying at the bottom of the tank. The anodes were of aluminum alloyed with 15 per cent. of tin; conductors 1¾ and 2 inches diameter respectively, otherwise same as acid-copper tanks. Time of



NEW ENGLISH DECORATIVE LAMP.

plating, 72 hours; four volts, 2,500 amperes. The resulting deposit of aluminum, 2½ ounces. The next and last treatment, that in the

6. Water tank, also of wood, same dimensions as copper-acid tank, filled with clean water at about 210°, in which the article was thoroughly cleaned by immersion and stream from a hose applied repeatedly.

Eventually, to expedite the work, two more tanks were added—one acid-copper and the other aluminum. These were of plate-iron and were placed directly upon the floor in the south space near the dynamos; they were about 12 feet square and four feet deep; otherwise they were arranged like the larger tanks for the same purpose.

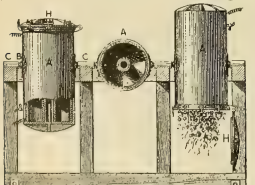
Before proceeding with the plating, the parts to be plated, after being completely fitted in place, during the preliminary erection at the works, were, upon their reception in the plating department, carefully tagged with the number and location on a sheet of brass, wired to the respective part, to which it remained attached until ready to fix in place at the building.

Upon the completion of the treatment in the alkali tank, and previous to treatment in the acid-copper tank, the article was carefully examined, and all pin-holes or other defects cleaned and filled with solder composed of tin and lead. Likewise, when the article had received its deposit of copper, it was again examined, the thick edges, which tended to form in the acid-copper tank, removed by filing, and, in the event of blisters having formed, they were cut out and the piece subjected to a second treatment for copper.

The accompanying illustration gives an interior view of this unique plating plant. One of the 1,000-pound columns is shown in the bath.

New English Decorative Lamp.

The accompanying picture shows (half size) a new type of ornamented incandescent lamp made by an English company. It is rather different from the usual forms of decorative lamps seen in this country and will interest the readers of the Western Electrician. It is interesting to note that the lamp is "guaranteed British manufacture," showing that



CARBONIZING PEAT BY ELECTRICITY.

the competition of imported lamps is a real factor in the lamp trade in England. The lampmakers of this country are eager to take advantage of any "talking point," but they do not have to guarantee American workmanship, as no other is known.

Carbonizing Peat by Electricity.

It is well known that to utilize peat to the best advantage it is first necessary to drive off the volatile portions, which consist of useless and noxious gases, and carbonize the mass. Heretofore this has been accomplished principally by means of furnaces specially constructed for the purpose, but now, M. P. Jebsen, according to la Revue Industrielle, has devised a method of accomplishing this result by means of electricity.

Upon a wooden frame mounted on rollers are arranged three swinging retorts, supported on centers C, as indicated in the cut. The left retort shows the internal arrangement; the middle one shows an end view with the cover removed; the third shows the retort being discharged.

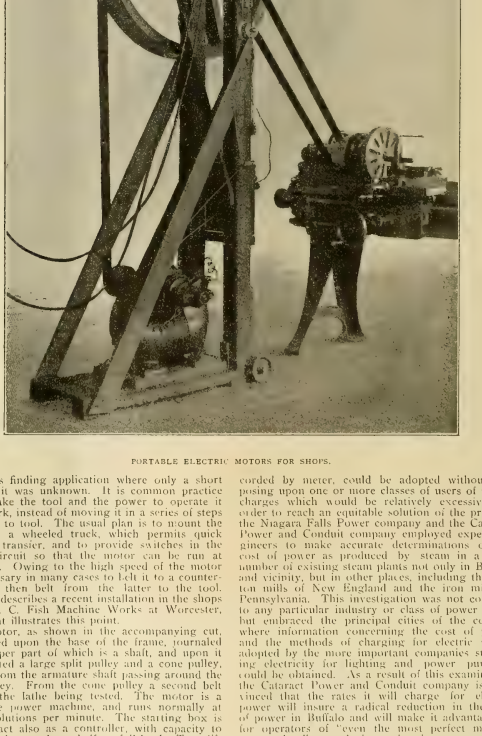
The retorts are lined with asbestos or other non-conductor of electricity and heat, which is wound spirally with an iron wire. Another winding is embedded in asbestos surrounding the core. These wires form suitable resistances for developing heat from the electricity traversing the conductors, through the terminals which are connected at the axles. Vents are established by means of stop-cocks, through which moisture and gas are permitted to escape.

The turf or peat is thus heated uniformly and thoroughly, as well as more exactly than by the method formerly employed, thus saving destructive burning and insuring a saving of 10 to 20 minutes besides.

Portable Electric Motors for Shops.

In general shop work the electric motor is recognized as a valuable factor, and in many special cases it is finding application where only a short time ago it was unknown. It is common practice now to take the tool and the power to operate it to the work, instead of moving it in a series of steps from tool to tool. The usual plan is to mount the motor on a wheeled truck, which permits quick and easy transfer, and to provide switches in the general circuit so that the motor can be run at any point. Owing to the high speed of the motor it is necessary in many cases to belt it to a countershaft and then belt from the latter to the tool. Iron Age describes a recent installation in the shops of the H. C. Fish Machine Works at Worcester, Mass., that illustrates this point.

The motor, as shown in the accompanying cut, is mounted upon the base of the frame, journaled in the upper part of which is a shaft, and upon it are mounted a large split pulley and a cone pulley, the belt from the armature shaft passing around the large pulley. From the cone pulley a second belt leads to the lathe being tested. The motor is a two horse power machine, and runs normally at 1,200 revolutions per minute. The starting box is made to act also as a controller, with capacity to cut down the speed one-half on full load. Two different sizes of cone pulleys can be used on the upper shaft, according to the size of lathe being tested. The two small wheels shown on the base of the frame, just clear of the floor, are for use when moving the device around the shop. The frame is simply tipped forward until these wheels touch the floor, when it becomes its own truck. The lighting system of the works can be tapped at any desired location, and current secured for the operation of the motor.



PORTABLE ELECTRIC MOTORS FOR SHOPS.

Cost of Niagara Power in Buffalo.

A statement of the rates at which power transmitted electrically from Niagara Falls to Buffalo shall be disposed of in the latter city has been prepared by the Cataract Power and Conduit company of Buffalo. It was found upon investigation that the requirements of the consumers and the conditions under which they operated were such as to make a uniform rate impossible. As a result of the wide range in the amounts of power which must be available and of the radical differences in hours of use, it was determined that neither the so-called flat-rate system under which each user is charged a certain amount per horse power kept at his disposal, nor the ordinary method of charging by meter under which each user pays a certain amount fixed by schedule for the actual number of kilowatt-hours or horse power hours used, as recorded by meter, could be adopted without imposing upon one or more classes of users of power charges which would be relatively excessive. In order to reach an equitable solution of the problem the Niagara Falls Power company and the Cataract Power and Conduit company employed expert engineers to make accurate determinations of the cost of power as produced by steam in a large number of existing steam plants not only in Buffalo and vicinity, but in other places, including the cotton mills of New England and the iron mills of Pennsylvania. This investigation was not confined to any particular industry or class of power users, but embraced the principal cities of the country where information concerning the cost of power and the methods of charging for electric power adopted by the more important companies supplying electricity for lighting and power purposes could be obtained. As a result of this examination the Cataract Power and Conduit company is convinced that the rates it will charge for electric power will insure a radical reduction in the cost of power in Buffalo and will make it advantageous for operators of "even the most perfect modern steam plant" to substitute electric power transmitted from Niagara for the present equipment.

Niagara power will be distributed from sub-

stations, and will be supplied in the form of three phase alternating current to all points within distances which can be conveniently reached.

Sub-station No. 1 adjoins the power house of the Buffalo Railway company, on Niagara street, and No. 2 is located on Ohio street, near Indiana street. The transforming machinery for sub-station No. 3, on Wilkinson street, is now under construction and will soon be ready to supply power.

A charge will be made for service, and, in addition thereto, there will be a distinct "charge for power." The "charge for service" is $1 per kilowatt per month (about 75 cents per horse power per month) and this will depend only upon the amount of power which the user may require the Cataract Power and Conduit company to keep available and ready for his use.

The monthly "charge for power" will depend upon the actual amount used, as determined by standard meters installed by the Conduit company upon the premises of the consumer. These meters will record the number of electrical units or kilowatt-hours actually taken by the consumer. The charge for power will be determined by the record of the meter and by calculation from the following schedule:

For use not exceeding 1,000 units, the rate shall be two cents ($.02) per unit.

For use exceeding 1,000 units, but not exceeding 2,000 units, the rate shall be: For 1,000 units two cents ($.02) per unit, and for the excess one and five-tenths cents ($.015) per unit.

For use exceeding 2,000 units, but not exceeding 3,000 units, the rate shall be: For 2,000 units one and five-tenths cents ($.015) per unit, and for the excess one and two-tenths cents ($.012) per unit.

For use exceeding 3,000 units, but not exceeding 5,000 units, the rate shall be: For 3,000 units one and two-tenths cents ($.012) per unit, and for the excess one cent ($.01) per unit.

For use exceeding 5,000 units, but not exceeding 10,000 units, the rate shall be: For 5,000 units one cent ($.01) per unit, and for the excess eight-tenths of a cent ($.008) per unit.

For use exceeding 10,000 units, but not exceeding 20,000 units, the rate shall be: For 10,000 units eight-tenths of a cent ($.008) per unit, and for the excess seventy-five hundredths of a cent ($.0075) per unit.

For use exceeding 20,000 units, but not exceeding 40,000 units, the rate shall be: For 20,000 units seventy-five hundredths of a cent ($.0075) per unit, and for the excess seven-tenths of a cent ($.007) per unit.

For use exceeding 40,000 units, but not exceeding 80,000 units, the rate shall be: For 40,000 units seven-tenths of a cent ($.007) per unit, and for the excess sixty-six hundredths of a cent ($.0066) per unit.

For use exceeding 80,000 units, the rate shall be: For 80,000 units, sixty-six hundredths of a cent ($.0066) per unit, and for the excess sixty-four hundredths of a cent ($.0064) per unit.

Pleasing Electrical Sign.

The picture given below is a reproduction of a prominent electrical sign on State street, Chicago. The sign is a particularly effective one, even on a street that is ablaze with similar advertising devices at night, as the letters have the appearance of standing out from hemispheres, although in reality the painted background is flat. It was made by the Chase Electric Sign company.

Magnetic Ore Separators.

From an early date the idea has been entertained of separating magnetic from non-magnetic substances by the use of the magnet, but up to a very recent date it had hardly been thought of to do more than separate iron from other substances, or mag

primary batteries then in use. With such sources the cost of the electric current was, however, too great to warrant a very extended use of magnetic separators, and until the invention of the dynamo machine reduced the cost of electrical energy inventors and users of such separators generally had to content themselves with such results as could be obtained by the use of permanent steel magnets.

The advent of the dynamo machine, however, gave a new impetus to the design of magnetic separators, and from 1880 to the present time a great variety of such machines have been invented, making use of electro-magnets energized by means of currents from dynamo machines.

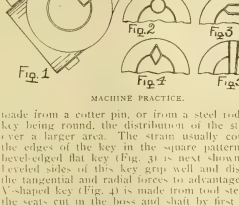
Machine Practice.

A contributor sends the following elementary explanations and simple suggestions for the benefit of such of the electrical mechanics who read the Western Electrician as are not too learned to profit by them.

Keys and Key Seats.

Keys and key seats in shafts and fittings on electrical machinery are necessarily varied in design, owing to the variety of the work performed. The common way is to sink a seat in the boss and drive in a square key, as in Fig. 1. The service performed by some of the high-speed shafts and the constant strain on the key make it impracticable to use this form. In order to avoid the liability of bursting the boss, round, V-shaped or beveled keys are often used, as shown in Figs. 2, 3 and 4.

The round key (Fig. 2) is put in by boring the boss and shaft together and driving in a round key



MACHINE PRACTICE.

made from a cotter pin, or from a steel rod. The key being round, the distribution of the strain is over a larger area. The strain usually comes at the edges of the key in the square pattern. The bevel-edged flat key (Fig. 3) is next shown. The beveled sides of this key grip well and distribute the tangential and radial forces to advantage. The V-shaped key (Fig. 4) is made from tool steel, and the seats cut in the boss and shaft by first boring round, then shaping with files. The advantage of this form of key is that the force applied is expended against the angles of the sides. The straight-

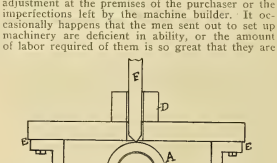


Fig. 6

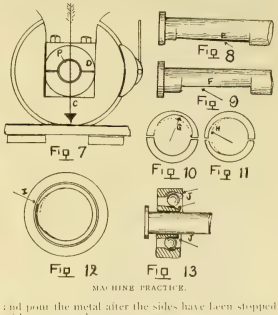
MACHINE PRACTICE.

obliged to slight their work in order to turn off an amount that will be satisfactory to their employers. Then, too, the best of machinery requires care.

A shaft rests upon its bearings according to load pressure and general conditions. Say that the weight is above the center C (Fig. 7), and the wear upon the bearings is at P. The belt pressure tends, for example, to place the point of friction at about D, so that if we examine a number of shafts, we may find that they are worn at E (Fig. 8) and at F (Fig. 9). Other bearings will be seen worn as at G (Fig. 10), and at H (Fig. 11). Fig. 12 shows how the metal sleeves are sometimes worn with balls. This is shown in section in Fig. 13. The worn places are marked I in the former and J in the latter. The ring is also worn. To replace the rings with new, great care must be used in forging the blanks from which the rings are turned, to make sure that the metal is not overheated and yet shall fill the dies. A good system of ring turning is to employ two tools working together, one on the inside, the other on the outside of the flange. This insures substantial concentricity of flange. The hardening of rings is also of the utmost importance. Rings not hard enough or unevenly hardened will wear out rapidly. Rings hardened too much, that is to say, rings hardened at either too high a degree of temperature, or exposed to heat for too long a time, become changed in character, the metal becoming granulous and rotten, and the surface becoming glassy and non-effective. As to the babbitting of the worn shafts and sleeves, first clean off all foreign matter and build up the shaft to its proper place in the box, by means of blocks on the outside,



MACHINE PRACTICE.

and pour the metal after the sides have been stopped with putty or clay.

Adjusting Circuit Breakers.

See that the latches of the dial needles are perfectly covered by the guide; if they are not it shows that the cam is throwing them out too far. To overcome this, remove the cam from the dial and take a little off the point that pushes the needles to their farthest point. If this cam is put in there will not be much trouble with breaking of needles or dial slots. Set the cam in dial just far enough so as to allow the needle to clear itself. If the latch does not close tight enough there may be dirt or dust under it. If there is, it may be removed by a piece of fine wire sharpened at the end. Use nothing but good oil on cylinder and dial, so as to keep them from getting hotted or rough. Common machinery oil will soon ruin them and make them a constant worriment to the one who has them in charge.

PLEASING ELECTRICAL SIGN.

nesite and perhaps pyrrhotite from other ores. The magnet has been used for separating iron chips and turnings from the brass chips collected in shops where both metals are worked together. Special magnetic separators have been devised for the separation of iron from rags used for making paper and for separating from paper pulp the finely divided iron that is ground up with the rags in the paper engine or that comes from the wear of the engines themselves.

Numerous magnetic separators have also been devised for separating magnetite from other ores or from other substances with which it is often found associated, and descriptions of such machines in which electro-magnets were used will be found among the patents granted nearly 50 years ago, when the only source of the electric current were the

through key in Fig. 5 is serviceable in certain cases in which the work is moderate and the speed not high.

Drilling and Slotting.

Fig. 6 shows a device for drilling and slotting key seats and pins of the type shown in Fig. 5. The piece A to be drilled is adjusted on the bevel pieces C C. The latter pieces can be adjusted to a center by means of the screws. Top adjusting screws E E allow the drilling tool guide F to be set as desired. Any mechanic can make one of these devices.

Worn Bearings.

The writer is aware that many things have to be done with old machinery that would be utterly impracticable on new. Yet it may be proper and necessary, under the circumstances, in order to get good work. The bearings should have careful attention. But before adjusting and overhauling the bearings, see that the machine is set up so that the different parts are fitted properly, made level and plumb, especially such parts as relate to the most vital parts, and particularly when running at high speed. Manufacturers of electrical machinery are blamed sometimes for faulty design when the trouble is wholly with the machine, either in the adjustment at the premises of the purchaser or the imperfections left by the machine builder. It occasionally happens that the men sent out to set up machinery are deficient in ability, or the amount of labor required of them is so great that they are

TELEPHONE, MAIN 1746.

EASTERN OFFICE: 108 TIMES BUILDING, NEW YORK.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Concise, well written articles are especially welcome; and communications, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN — **the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own.* THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNUSUAL VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

HIGH WATER MARK

CIRCULATION, 20,000.

State of Illinois, County of Cook—ss.

Frank Foster Kenworthy being duly sworn deposes and says that he is president of the city of Chicago, in the county of Cook and state of Illinois, and that he is the superintendent of the binding department of the Electrician Publishing company, the publishers of the Western Electrician; that he was present at and superintended the binding of No. 24 of Vol. 20 of the Western Electrician, issued on June 12, 1897, and that there were sent out by actual count 20,000 complete copies of said Western Electrician of the volume and number above specified.

And further this affiant sayeth not.

FRANK FOSTER KENWORTHY.

Subscribed and sworn to before me this 27th day of July, 1897.

Illustrated Electrical Patent Record 248

To most of the men engaged in the electrical industries in this country, war is, fortunately, a new experience. Nevertheless there will be no attempt to evade its responsibilities or to shirk the supreme duties of citizenship, which, in the last analysis, must override all purely private or selfish considerations. The war is a just one and it will be supported by a united country; men of all sections, all industries, all shades of opinion in other matters, will uphold the hands of the government. In this patriotic duty it is certain that the electrical fraternity will be most earnest and active. To such assistance as it can give, the Western Electrician pledges itself, and it will also endeavor to give some account of the applications of electricity in warfare as they are subjected to the grim test of service.

While it would be foolish to underestimate the serious nature of the campaign in which the United States has engaged and its effect on business enterprises, we think that if all survey the situation calmly and carefully balance the probabilities of actual hostilities there need be little disturbance of present industrial conditions. The military and naval operations should be pushed with all rapidity compatible with prudence. We trust the war will be short, sharp and decisive, and do not anticipate that the demand for electrical products, for instance, in this great country of 70,000,000 people will be seriously curtailed. As the New York Commercial said in a thoughful editorial printed a few days ago, "There is no danger of financial stringency or a disorganization of commercial confidence. Most of the fears which induce ultraconservatism are groundless. The idea that Spain can seriously injure American commerce is an exaggerated one. A little demonstration will convince people that they have overestimated the effects of hostilities, and if Spain should stick to its policy of resisting the inevitable and war is the only cure for its infatuation, it will be the real and only sufferer."

We find in the Iron and Coal Trades Review of London of recent date a brief description of the artificial moon in the reading room of the "Columbia (U. S.) State Library." Now, we would like to know what our New York friends think of that.

An excellent idea of the telephone situation in Great Britain can be gained from a perusal of the report of the discussion of the subject in the House of Commons, April 1st, which is presented in another place this week. The English method of handling this subject will be followed with interest by telephone men in this country. It is probable that upon the expiration of the present franchises the monopoly will be terminated or transferred to the government.

Attention is directed to "the arc as a telephone" by E. E. Fournier d' Albe, in the London Electrician. He explains that if the circuit of an arc lamp happens to be close to another circuit traversed by feeble intermittent currents, the arc emits a loud rattling noise. The intermittent currents may be produced by a tuning-fork interrupter, or by the hammer of a small induction coil. They produce in the arc circuit intermittent induced currents, and the latter affect the temperature of the arc and produce the noise. That the noise is due to the arc itself, and not to the regulating mechanism, is proved by the fact that the sound is heard equally clearly when the carbons are a fixed distance apart.

The phenomenon was discovered by H. T. Simon, who attempted to obtain a photographic record of the flickering of the arc, but failed because the changes of brightness are too slight in comparison with the total brightness. On placing a microphone in the primary circuit, the note of a tuning-fork and the sounds of whistling, tapping and singing were reproduced by the arc, with every detail of intensity, pitch and quality. Experiments made with a shunt circuit showed that the quantity of electricity capable of producing an audible sound was 5×10^{-6} coulombs, corresponding to a change of temperature of 0.3°C. Sound waves acting upon the arc direct produced changes of density and fluctuations of the current, which could be transmitted to a distance and reproduced by a telephone at the other end. Further investigations are now being conducted.

Occasionally the advocates of municipal ownership of quasi-public enterprises are confronted with the old-fashioned idea that public funds should not be devoted to any business that could be conducted by private capital, and that it is only where public safety or public health is concerned that governments are justified in exercising their power of control. An instance of this kind is presented in the case of "Mayo against the town of Washington," a municipal corporation containing a population of 5,000 inhabitants. The Supreme Court of North Carolina last month decreed that the purchase of an electric-light plant for the town, at the price of $20,000, simply to light its streets, was not a "necessary expense" pertaining to its government. The power to establish electric-light plants and waterwork plants, the court explains, stands on substantially the same footing. The importance of the decision will be appreciated when taken in connection with the provision of the constitution of the state which prohibits municipal corporations from contracting debts or levying taxes, except for necessary expenses, unless by a majority vote of the qualified voters of the corporation. The decision is significant, too, on account of the high standing of the court.

If the owner of a patent applies to the Patent Office for a reissue of it, and includes among the claims in the application the same claims as those which were included in the old patent, and the primary examiner rejects some of such claims for want of patentable novelty, by reference to prior patents, and allows others, both old and new, does the owner of the patent, by taking no appeal and by abandoning his application for reissue, hold the original patent, the return of which he procures from the Patent Office, invalidated as to those of its claims which were disallowed for want of patentable novelty by the primary examiner in the proceeding for reissue?

This question was raised in the United States Circuit Court of Appeals during the hearing of arguments in the case of the McCormick Harvesting Machinery company against C. Aultman & Co., and because of its vital importance was immediately certified to the Supreme Court of the United States for consideration and final adjudication. The latter tribunal has handed down its decision, which answers the question propounded most emphatically in the negative, and supports its position by an unusually interesting opinion.

The court says that it has been settled by its repeated decisions that when a patent has received the signature of the secretary of the interior, countersigned by the commissioner of patents, and has had affixed to it the seal of the Patent Office, it has passed beyond the control and jurisdiction of that office and is not subject to be revoked or canceled by the president or any other officer of the government. It has become the property of the patentee and as such is entitled to the same legal protection as other property. The only authority competent to set a patent aside or to annul it or to correct it for any reason whatever is vested in the courts of the United States, and not in the department which issued the patent. In this respect a patent for an invention stands in the same position and is subject to the same limitations as a patent for a grant of land. Moreover, while an original patent for an invention, if found inoperative or invalid by reason of a defective or insufficient specification or because too much has inadvertently been claimed as new, may be surrendered and a reissue may be granted, the Supreme Court says that such surrender takes effect only upon the issue of the amended patent. Upon application being made for a reissue, it says that the Patent Office was authorized to deal with all the claims, the originals as well as those inserted first in the application, and might declare them to be invalid, but such action would not affect the claims of the original patent, which remained in full force, if the application for a reissue were rejected or abandoned. This decision settles an important point in patent law which has long been in dispute and which has at some time been brought up in the experience of every inventor who has had much to do with the Patent Office.

WAR NEWS.

Congress transmitted a joint resolution on April 19th recognizing the rightful independence of the people of Cuba and demanding that Spain evacuate the island, at the same time directing the president to use the army and navy to carry the resolution into effect. On the following day the president signed this resolution, thus making it a law, and also sent an ultimatum to Spain. This action is tantamount to a declaration of war.

Harbor Defense.—The work of protecting the harbors of the Atlantic coast by mines, torpedoes and searchlights to be electrically operated, and of providing means of electrical communication between forts and other coast defenses, proceeds with great vigor, as shown by the reports from Boston, New York, Fort Monroe, Savannah, Charleston, New Orleans and other places. Captain Allen, the chief signal officer in New York harbor, is reported as saying that the wire needed for equipping the range-finders and position-finders at the various forts has nearly all been put in place and that the cable connections are practically completed. From Fort Monroe comes a rather curious story of the utilization of an old invention. It is said that a type of circuit-closer invented by Frederick G. Kipper, a private at the post, 12 years ago, was adopted for use in connection with the electrical circuits to be used in firing the submarine mines in Hampton Roads. The invention has been stowed away in the fort for 10 years, and has now been selected as the most ingenious and simplest of 12 devices. The engineers at this fort are actively preparing to have the submarine mines all ready to plant in Hampton Roads just as soon as war is declared.

A correspondent of a New York paper makes the unique but impracticable suggestion that the United States might countermine Cuban harbors—that is, plant mines and torpedoes outside of the Cuban mines and thus prevent the ingress or egress of Spanish war vessels. All that is needed, he says, is "the electric spark and a long cable" after the torpedoes or mines are placed.

From the very nature of the operations, very few persons—military men, electricians or others—are familiar with the exact method pursued in laying down submarine mines or torpedoes to be electrically fired from the shore to destroy a hostile ship. The New York Sun of recent date published a readable article on the subject, and although, judging by the electrical part of it, it can hardly be accepted as authoritative, still it contains many statements of general interest. A portion is quoted:

Mines for obstructing the approaches of an important position will be disposed upon one or more of four systems—grand groups, skirmish lines, detached groups and self-acting mines. The last absolutely close the approach to a harbor or channel to all ships; the others offer a safe passage to friends, either through a narrow unobstructed lane, or, with certain precautions, over the mines themselves. As for mines now being planted in the Narrows and at Sandy Hook, the general plan is to have a skirmish line for the exterior obstruction. This is arranged as follows: A large loop of single-conductor cable is laid with both ends in the mining casemate, from which every mine in the system is fired. This main cable is tapped every 250 feet, and a short cable leads from each of these points to a mine, usually 100 feet away to the front. The mine thus planted is fired by the contact of the enemy's ship with the torpedo. The electric current is always on, and the circuit is completed by the contact with the enemy's ship, causing the explosion. This system bears the same relation to the regular grand groups that a skirmish line of soldiers does to a line of battle. It increases the number of mines in a channel at comparatively slight expense, and, moreover, extends the area of danger to the hostile ships throughout a wide zone in front. By its use the enemy is forced to take precautionary measures a long distance from the defended fort in front of the principal lines of defense. The cost of a skirmish line in ordinary channels is about $6,000.

A grand group contains 21 mines, separated from each other by spaces of 100 feet and covers a front of 700 yards. All of these mines are operated through a seven core multiple cable, each core being connected with three mines through a water-tight insulated chamber. When set for automatic firing, only the mine struck by the enemy's ship explodes. The mines on each core may, if occasion arise, be fired simultaneously. Skilled engineer soldiers can lay a grand group in about 13 hours. From the mining casemate, which is usually near the level of low water, yet sheltered from bombardment as much as possible, the seven-stranded multiple cable extends to a grand junction box. Here the cores diverge as seven single-conductor cables, radiating like the ribs of a fan toward the enemy. These branch cables terminate in triple junction boxes 300 feet apart. At each of these points the cable again radiates through a water-tight insulated three-chambered receptacle, called a cut-out box, into three single-conductor cables, each terminating in a mine, which is a 500-pound ground mine, if the harbor or channel depth is less than [illegible] feet, or a bouyant mine of half that weight if there is a greater depth. In the latter case a buoy should mark the position of the explosive bulb, whose submergence is regulated by an anchor. Two of these mines are planted on the line of the triple junction boxes and one in front of it toward the enemy. The total cost of a grand group for service varies with the depth of the water and the strength of the current from $6,000 to $9,000, adding about $1,600 a mile for the multiple seven-stranded cable required between the group and the mining casemate. From this place every mine may be fired by turning the proper switches upon a switch or operating board to which all the torpedo cables run. At the proper time the man on the lookout for hostile ships telephones to the casemate, and the electric spark is sent upon its deadly mission at the proper moment. Detached groups and self-acting mines explain themselves by their names. The cost of one mine of the latter class is $250.

The work of mining with dynamite torpedoes the channel between Fort Schuyler and Willets Point began last Thursday [April 7th]. The flotilla used for the work consists of a steam tug with a crew consisting of one non-commissioned officer of engineers, one private, an engine driver and a steersman, one grand junction box boat with crew, and three triple-junction box boats and crews. One of the smaller boats accompanies the tug in laying the multiple cables as soon as the position of the grand-junction box has been located. This is done by placing the boat at the intersection of the axes of two theodolites, whose position is taken from an engineer map of the harbor or channel to be mined. The triple-junction boxes are then laid, and finally, after the necessary soundings have been taken, the mines are dropped at the proper measured distances from these last boxes and the connections are made from the box through a well-insulated cable.

Linemen of the Western Union Telegraph company are connecting the life-saving stations along the Long Island coast with the fortifications on Long Island and with Governor's Island. Connections will also be made with the Brooklyn navy yard. One object for making these connections is to enable the commanders of the scout boats that are to patrol the Long Island coast to make quick reports to the nearest army and navy headquarters.

Capt. Caspar F. Goodrich of the navy has perfected all arrangements for the new signal system by which quick and accurate communication can be carried on between vessels and shore stations. The entire coast line, from Maine south, has been divided into signal districts, nearly corresponding to the present lighthouse districts, with headquarters of the general superintendent in New York city. The first district comprises the entire New England coast and includes these light stations: Monhegan Island, Maine; Cape Elizabeth, Maine; Appledore Island, New Hampshire; Cape Ann, Cape Cod, Gay Head and Block Island. The second district, with headquarters on the receiving ship New Hampshire, in New York city, includes the light stations at Montauk Point and Iquoque, Long Island; Fire Island, Barnegat, N. J., and Cape Henlopen, Del. The third district will have headquarters at Norfolk, from which orders will be given for the conduct of the stations, which are at the lighthouses at Cape Henry, Point Lookout and Cape Fear. The fourth district will have headquarters at Charleston, S. C., and includes these stations: Charleston, Hilton Head, Tybee Island, and South Simons Island. The fifth district will have headquarters at Jacksonville, Fla., the first station being at the mouth of the St. Johns River, the next at Cape Carnavaral, then Jupiter Inlet and Miami. The sixth district will be at Tampa, and will include stations all around the southern Florida coast. From Florida to Louisiana will be another district. The semaphores and signal equipment have all been secured and are ready for distribution.

Status of Military Telegraphers.—Representative Belknap of Chicago is credited with the desire to give proper recognition to the telegraphers who may serve in the war that seems inevitable. He has a plan for organizing the telegraph branch of the military service into an officered department, having rank and prestige with the medical corps. For years, as is truthfully stated by a writer in the Chicago Record, it has been the grief of the old-time military telegraphers who served in the civil war that after hostilities ended they were sent back to civil life with no recognition whatever of their difficult and perilous work. They were regarded simply as civilian hired men, and, although what they did was of far more importance than many actions which brought promotion and honors to officers, nobody ever heard of it. The ordinary pension rules did not apply to them, and do not to this day, for they have never been given military status. The old operators for years have chafed under this state of things, and now that army fighting appears imminent once again, the younger generation of telegraphers is likewise interested. Mr. Belknap, expressing hearty sympathy with the matter, has taken the question before the committee on military affairs, of which he is a member, and, although the present situation makes such a measure improper of entertainment, it will be called forward as soon as an actual condition of war exists.

Submarine Torpedo Boats.—A particularly successful trial of the submarine boat Holland was made on Saturday last near Perth Amboy, N. J. The Holland went down until there was between three and four fathoms of water over its deck, and then for 12 minutes scudded along at full speed, nearly 10 knots an hour. The boat made three dives, and when the inventor came to the surface after the last one he declared himself better satisfied than ever that his submarine boat is a success. Part of the time the Holland was under water it was scraping bottom, and the pressure gauge in its conning tower showed that at times that there was fully 25 feet of water over its tower.

The submarine boat Plunger, also of the Holland type, building at the Columbian Iron Works, in Baltimore, is about ready for her sea trial. It has been said that she was only about 60 per cent. completed, but the officials of the Columbian company assert that it remains necessary only to overhaul her gas-fuel engines, a matter of a day or two, to render the boat ready for service.

These boats are operated by gas engines on the surface and storage batteries when submerged. They are equipped with compressed-air guns to discharge dynamite projectiles or torpedoes either above or below the surface of the water.

Observation Balloon.—A large observation balloon has been sent from Fort Logan, Colo., to New York, to be used in case hostilities are begun. It is 40 feet in diameter and takes 14,000 cubic feet of gas. It will be securely anchored to the ground and its maximum ascension will be about 1,800 feet. This is supposed to give a visual range of 150 miles. It would not be likely to be noticed by an enemy until he was within a few miles, for it forms a very small speck on the sky-line, when seen at any considerable distance, and even quite close at hand the enemy could hardly interfere with it, as modern armament is not built with a view to aerial gunnery. The balloon will be connected with the ground by telephone and supplied with searchlights and special observation glasses of great power. Should a Spanish fleet appear anywhere off the near-by coast, the first discovery would probably be from the balloon.

Floating Machine Shop for the Navy.—The Navy Department has purchased the ship Juniata, which will be converted into a repair ship and assigned to the North Atlantic fleet or the flying squadron. This is one of the precautions for which Engineer-in-chief Melville has contended for some time. A similar ship was equipped during the Chilean excitement. The Juniata is well adapted for this purpose. She is a steel vessel and will be fitted out with about $30,000 worth of tools and machinery. The work of equipment will be done at the Boston navy yard, where orders have been sent to accumulate the material needed. The ship will be commanded by an engineer officer, with four assistants, and volunteer naval officers will fill the places of executive and watch officers. The enlisted force will consist mainly of machinists and electricians. The Juniata will be prepared to repair any damage which may happen to the machinery of a vessel, also material external damages.

Miscellaneous Notes.—Lieut. S. D. Flood of the Northern Illinois batallion of naval militia, who has been an active figure in recruiting and drilling men for his division, is well known to electrical men, as he was for several years connected with the power and mining departments of the Thomson-Houston and General Electric companies.

The great activity at the Brooklyn navy yard has caused the officers in charge to make a recommendation that the electric-lighting facilities of the reservation be increased materially, so that night work about the yard and the drydocks may go on without being hampered. Some time ago plans were prepared for enlarging the illuminating plant, but there has been some delay (not an unusual occurrence at the yard) in securing a building of the Department of Construction and Repair large enough to accommodate the increased plant. As the building to which the plant will be transferred will not be vacant until July 1st, Civil Engineer Endicott of the Yards and Docks Bureau has recommended the allotment of $30,000 for the immediate construction of a temporary building for the purpose.

Apropos of the article on West Indian cables in the Western Electrician last week, it is interesting to note the dispatch from Madrid, printed in the American papers of April 18th, stating that Senor Moret, secretary of the colonies, has approved a contract to lay a direct cable between Cadiz and Havana, by way of Teneriffe and Vieque (Crab Island), nine miles east of Porto Rico. It is, of course, to be remarked that in all human probability this cable will never be laid.

One feature of the proposed war-tax revenue bill is a tax of one cent on every 25-cent telegraph message.

Prof. R. H. Thurston, director of Sibley College, Cornell University, is an engineer whose opinion carries weight. He has carefully examined the report of the Maine Board of Inquiry and asserts that it gives "proof, positive and absolute," of the facts that the ship was destroyed by an "exterior explosion," that it must have been that of a mine, and at the port side of the vessel, near the bow; that only an exceptionally heavy charge could have performed the destructive work; that such a mine could only have been set by expert military or naval engineer or ordnance officers. It could, therefore, he says, have been fired only by men officially connected with but not authorized by the Spanish government, and thus the case of the United States is made absolutely unchallengeable. He asserts that it is a duty on the part of all members of the engineering profession to examine these proofs as presented in that report, and the more so as they, next to naval and military men, will necessarily direct public opinion in relation to the responsibility.

A number of Chicago electrical men have already signified their intention of joining the volunteers as soon as the president calls for troops.

The students of the electrical engineering department of Purdue University, Lafayette, Ind., are to be especially favored this spring in the matter of visitors who will address them along professional lines. Prominent among the list of the non-resident lecturers at the university are the names of Samuel Insull and Albion E. Lang, who have already done much to advance the electrical interests of the country, and who stand at present among the most advanced thinkers and workers of America. Mr. Lang, who is president of the Toledo Traction company and of the American Street Railway association, will deliver an address at the university on the subject of "Electric Power Companies and Their Relation to Municipalities" on April 26th. Mr. Insull is president of the Chicago Edison company, of the National Electric Light Association and of the Association of Edison Illuminating companies. He will visit the university on May 17th, and will lecture on the subject of "The Development of the Central Station."

DEVELOPMENT OF THE TELEPHONE FIELD.

Massachusetts Telephone Bill Killed.

[Special correspondence of the Western Electrician.]

Boston, April 17.—The bill to place telephone companies in Massachusetts under state supervision, the full text of which was printed in the Western Electrician of April 9th, has been killed by the lower branch of the Legislature, where the bill originated. It passed several readings by a close vote, the question on ordering to a third reading being voted on April 1st, when the friends of the bill won by a vote of 75 to 61, with enough pairs recorded to place on record 200 of the 240 members of the House. On April 12th, on the question of ordering the bill to be engrossed, the opponents of the bill were victorious by a vote of 84 to 77, with sufficient pairs to place 209 members on record. The following day reconsideration was refused by a vote of 105 to 78.

The Massachusetts Legislature thus places itself in the position of taking a right-about-face on an anti-corporation measure. There seems to be no doubt that the Bell and New England companies used all the influence they possesed to defeat the bill. Representative Mead of Lexington said in debate on the floor of the House that the lobby employed against the bill was "the largest and most unscrupulous since the Bell telephone grab" several years ago. A survey of the corridors of the state house, while the bill was under discussion, would have led the observer to believe that the statement had some foundation in fact. The bill was a so-called popular measure, but its popularity with the people failed to overcome the powerful influence of the telephone interests.

The bill would probably have met its death in the Senate any way, but the action of the House is no less a disappointment.

An examination of the record reveals the significant fact that on the final roll-call members who had been recorded for the bill at previous readings or had been paired in favor of it either changed their votes or stayed away, in a sufficient number to defeat the measure.

Southern Telephone Notes.

The Knoxville, Tenn., Sentinel of April 12th contains the following paragraph: "Last week when Cattlet Tipton was placed in jail at Sevierville after he had been committed there by the jury who pronounced him guilty of the murder of William Whaley, there was a scene that was partly transmitted by the People's Telephone company to this city. Tipton was placed in a cell and afterward his wife was shown to his cell. Then began a crying spell of the wife and husband. So violent was the sobbing that it could be heard in the courtroom, 200 feet away, and disturbed the court. The position of the wife and husband was such that the sound had to travel to reach the telephone in a Z-shape course a distance of 50 feet. The telephone at the jail is connected with the exchange there, and there is 30 miles of wire between Sevierville and the exchange in this city. The sobbing of the wife and husband, as well as their words, could be heard in this city."

The People's Telephone and Telegraph company of Knoxville has just issued a directory of its local exchange subscribers and those of the independent companies in Maryville, Newport, Morristown, Greenville, Rogersville, Sevierville, Johnson City, Coal Creek, Trotters, Elizabethton, Jonesboro and Clinton. The company's stockholders are representative merchants and business men of Knoxville. The charge for service among twice as many patrons is less than one-half the former average price. The company asks its patrons to note the contrast in telephone facilities before this enterprise started with those of the present. The rates are 50 per cent. less, the service 100 per cent. better, the number of subscribers increased 400 per cent. and toll-line connections furnished with all East Tennessee. The offices and exchange are in the City National Bank building. The operating room and the details of the system employed have been described and illustrated in the Western Electrician. The officers are the following-named gentlemen: President, C. E. Lucky; vice-president, W. L. Welcker; general manager, J. C. Duncan; secretary and treasurer, Elmer D. Ross. The board of directors is composed of C. E. Lucky, W. L. Welcker, M. L. Ross, J. C. Duncan, Asa Hazen, E. G. Oates and A. J. Douglas.

Independent Movement in Lancaster County, Pa.

The independent telephone movement is making rapid strides in Lancaster County, Pennsylvania, where the Columbia Telephone company began business on January 1st. The initial exchange equipment comprised a 100-point switchboard. The company started with 50 subscribers connected, and since that time it has doubled the capacity of the exchange, and it has also increased its service to 150 subscribers' stations connected in Columbia. A pole line has been built to Marietta, and an exchange put in with one 50 point board, which opens up communication with Chick[illegible], Watts and Maytown. Work was begun on Monday, April 18th, on an extension of the line to Mountville, Lancaster County, and will be completed about May 1st. The Columbia company has also been granted franchises to build lines in Mount Joy, Elizabethtown, Lititz, Epraha, and these towns will be equipped with first-class exchanges and pole lines soon.

The switchboards and telephones to be used will be supplied by the Western Telephone Construction company of Chicago. The Columbia company has met with success since it has been in business, and is gradually driving the Bell people out of the towns on its lines. The managers of the York County Telephone company and Columbia company are to meet on April 20th and complete arrangements to connect their systems and adjust toll-line rates, which will add greatly to the strength of both companies. The officers and directors of the Columbia company are: President, H. C. Young; secretary, F. G. Pain; treasurer, Charles Rochow; superintendent, H. W. Johnson; William Mattern and M. R. Hoffman.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

C. G. Cockerill of Jefferson, Ia., has secured entire control of the Jefferson Telephone company, including toll and local-exchange lines. Mr. Bandy, heretofore a partner, now holds the lines south of Jefferson only. Mr. Cockerill is planning extensions to Grand Junction and other points.

The Canton, S. D., Telephone Exchange company has been incorporated to put in a local exchange. A line will be run to Moe, Alcester and Beresford.

Alfred Sundeen has made a proposition to put in a telephone exchange for Princeton, Minn.

The electric-light company at Knoxville, Ia., was granted a franchise for a telephone exchange.

The Iowa Mutual Telephone company has been refused an exclusive telephone franchise at Atlantic, Ia. Pat Boyle of Massena also asked for a franchise for a company which will build from Corning to Atlantic.

The Iowa Telephone company is working to put in an exchange at Villisca, Ia.

A local telephone exchange is proposed at Benson, Minn., and a stock company will be formed.

A telephone is in prospect at Cantril, Ia., to Memphis, Mo.

The Watterson, Ringgold and Caledonia Telephone company has been incorporated at Mount Ayr, Ia., and proposes to build to Hatfield, Mo. The poles are all set for the line between Watterson, Ringgold and Caledonia.

The American Telephone and Telegraph company celebrated its long-distance connection with La Crosse, Wis., by giving subscribers there a free concert over its lines, the music coming from a band in Milwaukee.

Rowe Brothers have the poles set for 40 miles on the line between Pierre, S. D., and Rapid City, and the holes are dug almost to Rapid City. They will begin stringing wire soon.

A Des Moines company has arranged to give long-distance connection for Cottonwood, Minn.

The New Ulm Telephone company of New Ulm, Minn., is preparing to build lines to Mankato, Evan, Morgan and Redwood Falls.

Fairhaven, Wash., is promised night service if 50 subscribers can be secured.

The Marshall-Wells Hardware company at Duluth, Minn., has just had a private branch-telephone exchange put in its building, with 20 instruments.

The Iowa Telephone company proposes a line from Cherokee to Primghar.

The towns of Humeston and Allerton, Ia., have both voted franchises for local telephone companies.

A telephone line is projected between Red Lake Falls, Minn., and Chester.

Arrangements are completed for putting in a telephone exchange at Eureka, S. D., at once.

W. K. Hind of Fairfield will succeed C. W. Bartlett as manager of the Mutual Telephone company at Des Moines. The Mutual company has 10,000 feet of cable being constructed to improve its service. The company is also interested in the new company which has been formed to build lines from Des Moines to Ottumwa, to include connection with Newton and Oskaloosa. Its office at Des Moines is to be enlarged, and operators are to have only 75 instead of 100 instruments to answer.

The Iowa Telephone company will construct about 900 miles of new toll lines, all to be metallic circuits, this year. The longest will be from Davenport to Des Moines, via Washington, Oskaloosa and Indianola, 222 miles. The next longest will be from Dubuque to Fort Dodge, 202 miles.

The Sparta Telephone company of Sparta, Wis., will extend its lines to connect with La Crosse, via Cashton and with Norwalk.

George Pfefferkorn has arranged to have work begun soon on the local telephone exchange at St. Charles, Minn.

An ordinance granting the American Telephone and Telegraph company a franchise in Duluth, Minn., has been introduced in the council. It provides against consolidation with any existing company, but has the right to use the subways, wires and poles of other companies. The council and mayor propose to hold off from granting any franchises until the new charter is in effect, if possible. At the same time the city wants long distance connection. The fear of the council is that in some way a franchise to the long-distance company will be used to extend the present company's franchise, which expires in 1899. Under the new charter the people will vote on all such franchises.

The Plainview, Minn., Telephone company will put in a metallic circuit between Hammond and Wabasha and buy a new switchboard.

The Woodbine Telephone company of Woodbine, Ia., will extend its lines soon. It expects to build about 50 miles of new wire this season.

The Union Electric Telephone company of Waucoma, Ia., proposes to build from Austin, Minn., to Albert Lea.

Cheaper Telephones Needed.

[From the New York Tribune.]

The annual meeting of the Bell Telephone company was held in Boston recently, and in his address the president declared that the output of telephones and the increase in the number of exchange subscribers was unprecedented in the business. He added that the gains in the pay stations in the last two years were equal to the aggregate gains of the six preceding years. The figures of the annual report showed a condition of marvelous prosperity. The total income for the year was $5,130,844, while the total income in 1896 was $4,327,324. An extremely large proportion of the income was clear profit, for the annual report states that the net income in 1897 was $4,169,674, and that dividends were paid for 1897 amounting to $3,682,948. The balance-sheet on December 31, 1897, showed total assets of $60,779,841. It also showed a reserve of $4,025,628, in addition to the surplus of $2,590,521.

It is evident from these statements and these figures that the Bell Telephone company has been one of the most gainful corporations ever organized in this country. Its proportion of clear profits to expenditures has been exceedingly impressive. When the telephone subscribers in New York reflect upon these figures they cannot fail to be unhappy, because they are still required to pay such large sums for telephone service. Not only are the rentals of telephones in this city plainly excessive in proportion to the genuine merits of the service given, but when any telephone subscriber in the borough of Manhattan wishes to talk to a subscriber in the borough of Brooklyn, in the borough of Richmond, or to a subscriber in any part of our suburbs, including Jersey City and other New Jersey places, an extra charge is imposed. People who are familiar with the actual amounts paid for telephone service in the borough of Manhattan must feel that they are paying too much for what they get. It is not intended to intimate that the profits of the company which owns the telephones in this borough or of the companies which control the telephone service in the vicinity of this borough are anything like so huge as the vast profits of the Bell Telephone company itself. When the users of the telephone all over the United States study the figures of the annual report of the Bell company, and when they inform themselves as to the low rates for telephone service in England and on the continent of Europe, it will not be surprising if they become impatient and restless because Americans are required to pay so much more in proportion for telephone communications than subscribers are compelled to pay in England and on the continent. The reduction of telephone charges has been fought at Albany and other state capitals with conspicuous ability, ingenuity and stubbornness. The unhappy subscribers of the borough of Manhattan are not likely to get service at reasonable rates until an agitation has been entered upon so active and so energetic that the Legislature will not venture to refuse a reduction.

It would be a gracious and generous act if the men in control of the corporations which own the telephones in this state and in other states would recognize the obvious fact that they have already made splendid profits out of the telephone monopoly, and that it is time for them to be more liberal and benevolent in their treatment of telephone subscribers and of the American people generally. Since the telephone first came into use the cost of travel in our cities and our communities generally has been much diminished. Consider the system of transfers on many surface lines in all the boroughs of this city and in many other cities, and it cannot be denied that in most of the important cities, town and villages of the country people now have ample opportunities for riding many miles in cable cars or in electric cars for low rates of fare. The tendency has been for years to give the public larger returns for moderate expenditure in many matters. Many kinds of clothing and many kinds of food can be bought much more cheaply than a few years ago. The charges for telegraph messages have been cut down a great deal since the telephone was invented. Officers of the local telephone company insist that their system supplies so many calls for the money paid that they are not making objectionable profits. But when the annual report of the Bell company sets forth the prodigious gains of that corporation the telephone subscribers in the borough of Manhattan cannot be convinced that the local telephone company is earning only fair and equitable profits on the amount of capital actually and honestly invested. New Yorkers are paying too much for telephone service, and the next Legislature should cut the rates sharply.

Telephone Situation in England.

The controversy over the telephone service in Great Britain has reached the stage where the House of Commons has taken notice of it. On April 1st the following resolution was introduced:

That the continued refusal of the Postoffice to grant licenses to and allow municipal corporations and other responsible bodies to compete with the National Telephone company is contrary to the Treasury minute of May 23, 1892, is inconsistent with the letter and spirit of the agreement entered into with the telephone companies when the Postoffice took over the trunk lines, and is calculated to prevent the establishment of a cheap, adequate and efficient telephone service in the United Kingdom, and to increase the difficulties and costliness of any arrangement for the assumption by the state of the whole telephone systems, should that step ultimately be considered desirable.

The debate lasted four hours and was devoted principally to the history of the development of the telephone service in Great Britain. Mr. Caldwell, who introduced the resolution, said that it was generally recognized that the subject was one of national and local interest and importance and one outside of party politics. He reminded the House that the Postoffice granted a license to the United Telephone company authorizing it to erect and work telephone exchanges in London within a radius of five miles from a central point to be fixed by the company, the royalty charged in all cases being 10 per cent. of the gross earnings. The United Telephone company confined its own exchange operations to London, but it allowed its apparatus to be used in other parts of the country by subsidiary companies. These subsidiary companies were left to negotiate with the Postoffice for a license. The licenses granted were all made to expire on December 31, 1911. At the date named, therefore, all telephone licenses would lapse and the state would then be free to assume the sole right of working the telephones. Until 1884 telephone licenses were restricted to towns and areas within a certain radius of towns. The Postoffice offered to supply trunk lines connecting towns on condition that the users should pay the department direct. This offer was not accepted, but in a few cases, as between London and Brighton, trunk wires were provided for the use of the telephone companies at a fixed annual rent. In all about 23 licenses were granted for telephone use in these restricted areas. In 1884 licenses, instead of being limited to a restricted area, were made to apply to every part of the United Kingdom, and included the right to erect and work trunk lines. The new licenses were granted to the original holders; but while the policy of the Postoffice was to increase the number of licenses and to encourage competition, the policy of the telephone companies was to buy up competing companies at almost any price, with the view of establishing a private monopoly. The amalgamation of the telephone companies then took place, and the probable effect did not escape the attention of the postmaster-general. Mr. Fawcett said that he was pressed on all sides not to allow a private monopoly to grow up and to be vested in a private company, and the policy of Mr. Fawcett continued to be the policy of his successor. The Treasury minute of May 23, 1892, restricted the granting of licenses to responsible companies who had the consent of a municipal authority, and who were not so likely to apply for a license merely in order to sell it to the National or other telephone company. But the interposition of the municipal authority in an application for a license was a very limited safeguard, and would not, unless the license was carefully restricted, prevent the National Telephone company from afterwards buying it up. The only effectual safeguard seemed to be to give licenses to such municipal authorities as were willing, with parliamentary sanction if need be, to establish and work telephone exchanges in the public interest. In 1892 the Postoffice found it to be necessary to revert to the original policy of restricting licenses to the limited area to which the license applied, and of keeping in the hands of the Postoffice all the trunk lines connecting the towns. In saying that municipal authorities ought to be granted the licenses in the public interest, it had to be borne in mind that the license asked for was a license to use what was the property of the state, which all parties seemed to think ought not to be in private hands, but ought to be worked in the public interest. He claimed the appearance of the amendment on the paper as an admission that the telephones ought to be worked in the interest of the public and not for private profit. The power to grant competitive licenses was the only weapon which the postmaster-general could use for the purpose of preventing the wholesale plunder of the public, who were compelled by business exigencies to use the telephone. In all other cases in which statutory privileges were granted to companies the dividends that could be earned or the rates that could be charged were limited or subject to control. But the telephone company might water its capital to any extent, could charge what rates it pleased, and could run up the market value of it shares to any extent in the hope that in 1911 it might compel the government to purchase the undertaking at as ruinous a cost to the taxpayer as the cost of purchasing the telegraphs. The only means of ensuring an efficient telephone service at a moderate tariff was by the use of the reserved power of granting competitive licenses. In the hands of a municipality the service would be extended to the full extent, and small tradesmen and business men would get the benefit of it at a reasonable rate. In Glasgow the National Telephone company seemed to think that it was to its interest to keep up the present high tariff of £10, and not to encourage additional subscriptions by making a reduction. The corporation of Glasgow, however, was satisfied that an efficient service could be supplied at £5 a year, and that the present number of subscribers would be doubled if the price was reduced to that figure. Why should the Postoffice refuse to a corporation like that of Glasgow a competitive license, such as the department formerly granted so frequently to private companies? The fact was that the Postoffice officials objected to giving a license to a municipal authority because their own operations in connection with the telephone had failed so conspicuously, and they did not view with satisfaction the probable success of others in the enterprise.

Griffith Boscawen said his quarrel was not so much with the National company as with the Postoffice, which allowed the monopoly to grow up. He pointed out that what people most desired was a local service. The monopoly was growing stronger every day, and the sooner it was put an end to the better. He thought it would be well if an act were passed to enable all corporations to establish telephone services without having to come to Parliament for powers. At any rate, if the government allowed competition to spring up in some form or another, the action would be most acceptable to the country.

Faithfull Begg moved an amendment to leave out all after the first word in line 1 in order to add that

"The acquisition by the state of the whole telephone system of the country is the only solution of the difficulties which exist and are increasing under the present system of licenses."

It has been said that one of the objections to the present telephone system, on public grounds, was that it was under no stautory obligation in regard to tariffs and charges such as undertakings of a similar nature were placed under by Parliament. That was owing to the fact that at the time licenses were first granted there was little expectation that so great a development of telephonic enterprise would take place within a short period. The true solution of the question was that the state should acquire the whole telephone system of the country, combine it with the Postal Department, and develop it for the benefit of the community alone. There was a prevailing belief that at the expiration of the licenses in 1911 the government would be able simply to duplicate the existing system. But the system would by that time have expanded so much that he did not think the government would be able to leave it on one side without an interruption which the public would not endure. He hoped that under no circumstances would any license be granted to any private company, because the results would be even more pernicious than granting licenses to corporations. The confusion arising from having different systems in a town was terrible. Bad as he admitted the service in London to be, the confusion would be worse confounded if they had numerous systems growing up in the metropolis. State purchase, he was convinced, presented the true remedy.

Mr. Hanbury, financial secretary to the Treasury, said the motion before the House asked that certain municipalities should be allowed to enter into competition with existing licenses of the government in the same area. At first sight that might seem a rather strong suggestion, especially when it was borne in mind with regard to the telephone business generally, that there were great difficulties with reference to competing companies in the same area. He thought, therefore, the first question which the House would ask was whether it was fair that they should allow competition to take place; and in the next place, if it was fair, whether the municipalities of the country were the best form of competition. In the early days of telephones, when little was known about them, the postmaster-general of that day had to arrive at a decision as to the course that the government should take with regard to the new system. Mr. Fawcett in those days decided that the telephone service should be carried on by the government. If that had been done it might have been the best solution of the difficulty. However, the Treasury, rightly or wrongly, ruled otherwise. It imposed on the working of the telephones by the Postoffice certain conditions which he admitted did make the competition and working by the Postoffice very difficult. The result was that Mr. Fawcett, finding that the Postoffice could not work the telephones efficiently as a government monopoly, instead of granting local licenses, which he had done up to about 1884, limiting the companies to definite areas, instituted a system of entirely free competition. He announced in August, 1884, that he would grant licenses freely to every company that applied to him, and licenses which would extend all over the country, so that any company would be at liberty to set up exchanges in any portion of the country. His idea was that, if the monopoly could not be in the hands of the government, he would take steps as seemed to him best to prevent a monopoly falling into the hands of any private company. The result showed that Mr. Fawcett made a grave miscalculation. In the first place, he omitted to recollect that in those days one company, the United Telephone company, had a great advantage because it owned patents, and it was not possible for companies generally to get patents except under the rules and regulations of the United Telephone company; but the small companies were soon bought up, so that a series of companies came under the entire control of that company. Some of these companies did become somewhat strong competitors of the mother company, and in 1889 the United Telephone company bought up the Lancashire and Cheshire company and the National company, and they were amalgamated in the National Telephone company, which now worked the telephones. In 1891 the patents expired, and it then became possible for other companies to come into competition totally independent of the mother company. Two companies were started, the Mutual company and the New company. The New company soon bought up the Mutual, and that brought the New company and the National company face to face. The Treasury minute of 1892 was drawn up with the distinct recognition of competition as against monopoly. Very soon after the issue of the Treasury minute a very vigorous flirtation took place between the two companies, and they were all but amalgamated before the agreement was formally signed. Therefore Mr. Fawcett's anticipations were entirely falsified, and the very means he took to promote free trade in competition resulted in an actual monopoly. Now that one company had swallowed up all the other companies they had a very remarkable state of things. They had not only a monopoly, but one which was not under strict control or under stringent regulations. Their railway, water, gas and electric-lighting companies were all placed by Parliament under very strict limitations with regard to their capital, dividends, rates and, especially, preferences, and on all these points this telephone company was absolutely unfettered. He thought that that was a strange state of things. Without entering into any minute calculations as to the actual value of the plant of the company, while he believed its capital stood at a value of something like £6,000,000, the Postoffice calculation was that the plant could be entirely replaced at a cost of very little over £2,000,000. Then there was a further point which had resulted from the want of competition. When he looked at the little competition there had been he could not blame the company for its defects. He was rather astonished that its service was as good as it was. He wanted to recognize that in a good many parts of the country they were giving a service about which there was no great complaint; but at the same time in several large and important towns, even in the metropolis itself, and in Glasgow and other Scotch towns, there had been complaint made of the inefficient service; and in the case of Glasgow the complaint had been proved to be true by the government commissioner, and with regard to London Mr. Forbes himself had admitted the charge to a great extent. It was most important that the country should not be behind other countries, and it was no doubt the fact that at the present moment the number of subscribers in London did not compare favorably with the number in Berlin and Paris and in some of the smaller Scandinavian towns. There was also the fact to be remembered that the service was now confined to the more populous parts of the country, that very little had been done in the country districts, and that even in the populous towns, after all, the service was rather one for the rich merchant classes than for the smaller tradesmen, who could not bear the heavy subscription in order to get the benefit of the service. He did not blame the company for this. They had only taken advantage of the grave error committed by the Postoffice in 1883. Now they had to accept the facts as they were, and to try to make the best of a bad bargain. The figures he had already given showed that they would make a very bad bargain if they purchased the company at anything like the present market value. Although both in 1890 and 1897 it was possible for the government to give notice to purchase by arbitration, two governments in succession had decided not to exercise their option. It had also been definitely decided that these licenses would not be extended beyond the year 1911. The select committee which sat in 1892 said in its report that it was perfectly willing to leave everything else to the government, but that it must make some strong recommendation that the licenses should not extend beyond 1911. That being so, the government had undoubtedly to face this difficulty. The National Telephone company was in possession of the field at the present moment. It was extending very rapidly, and, he did not hesitate to say, becoming more formidable every year. If it was known that the licenses would expire in 1911, and if the government of that day did not agree to purchase, by notice or arbitration, the plant of the company, its assets generally, it might be, its good-will, and even the wayleaves the government had conceded to it, it was possible that the company, seeing that there were only a few years to run, might take the opportunity of trying to put the Postoffice and the Treasury in a difficulty —he did not say unfairly. Possibly the company would not agree to a bargain, and unless the government had started themselves very early, with an entirely new plant of their own, the company would be unwilling to sell to them, and raise their rates, with the result that there would be such an outcry in the country that the government might have to buy out the company at its own price. This evil, however, might be avoided to a limited extent by competition. What was the best form of competition? He did not believe that competition by companies would be by any means the proper course. Then competition by the Postoffice had not been a success, so far. He thought that the reason why the Postoffice had not competed, even in its own exchanges, was partly the idea that it ought to

work harmoniously with the company. With regard to the greater portion of the area of the country, he admitted it was necessary to work in amicable relations with the company. They must remember that those Treasury regulations, which were framed in 1882, and which caused Mr. Fawcett to throw the whole of this valuable service to open competition, were still in existence, but they now proposed to abolish them; they proposed to enable the Postoffice to try and canvass for work in just the same way as any private company. He was afraid that even when they had done that there was a difficulty which militated against the success of the Postoffice exchanges even more than the Treasury regulations. He had said already that the National Telephone company had got certain unrestricted privileges which, so far as he knew, were enjoyed by no other monopoly. It had got the privilege of granting preferences to particular subscribers, and by means of giving free wires or reduced rates to large men who would bring them a large amount of business, they did what the Postoffice exchanges naturally could not do, because they could not give preferences. A promise had been given over and over again by various postmasters-general in that House, and he had repeated that promise only last session, that if in any case where there was a dear or unreasonable service, and no competition it would be the duty of the Postoffice itself, if necessary, to enter the field and extend the exchange. There was the less objection to their doing so, because although the Postoffice might be blamed for not having worked its exchanges as vigorously as it might have done, still in spite of all the difficulties—and the question of preferences was a serious one—the Postoffice exchanges had paid the Postoffice a very large interest on the money expended. Therefore from a financial point of view there was very little reason why the Postoffice should not where necessary extend its exchanges, and if it did so of course it would be gradually preparing for the day when the whole of the telephone system would fall into its hands. Then they came to another class of competition which had hitherto not been dealt with. Until at any rate 1892 the municipalities were about the only bodies who could not well enter into telephonic competition with the company, because of the general licenses granted all over the country, including the right to work the trunk lines. The municipalities were the only bodies whose action must necessarily be confined to their own areas, and they were therefore shut out from competition. The municipalities or local authorities were perfectly willing, as he understood, to undertake licenses and to work them on condition that in 1911 they absolutely surrendered those licenses to the government. That was one argument undoubtedly in favor of the local authorities. Another argument was that they certainly would not be bought up as a company might be, and in addition they had wayleaves and would be able therefore to lay an efficient underground service. Municipalities argued also that, while they were willing to allow their streets to be taken up for their own exchanges, they did not wish those streets to be at the mercy of any private company. He thought there was a great deal of justice in that contention. Under the Treasury minute of 1892 the municipalities had an absolute control over any new companies, and no new company could work within the area of any local authority unless it got the permission of that local authority. Therefore if they were not going to allow the municipalities to compete he did not quite see what chance of competition there was from other sources. On the other hand, there were serious difficulties involving questions of policy which Parliament itself ought to decide. Even if they were to grant a license to the Glasgow corporation, for instance, although Glasgow had got a common fund, differing in that respect from the English corporations, it would not be able to exercise that license, and there would be no use therefore in doing so. There were two questions of policy to be considered in granting licenses to municipalities. Hitherto undoubtedly the telephone in England was more or less a luxury of the rich, although it was not confined to the richer classes in other countries. That was at any rate one question which the select committee which they proposed to appoint would have to decide—whether a telephone service was a matter of such general benefit to the community living within the area of a municipality or local authority as to justify the local authority in using public funds for the purpose of undertaking telephone work within the area. That was a question which a department ought not to decide, and which ought to be left to Parliament. There was this further peculiarity with regard to the telephone service, that there must be, even with regard to large municipalities, areas outside, which it would not be for the public convenience to include in the area of the municipal exchange. He was bound to say that by some means or other certain areas had already been assigned to the National Telephone company which even the largest municipality could not possibly embrace within its operations. The area of the exchange of London he was told, had 750 square miles—an area a good deal larger than even the London County Council would possibly attempt to work. He should have thought with regard to a large body like that, that if a license were granted to it it ought to be contented with its own area. What they proposed was to appoint a select committee of the House which should confine itself to two legal points, namely, whether any change in the law should take place which would, by the removal of restrictions, make it possible for a municipality to engage in such an undertaking, and how far this extension of the telephone system in the hands of persons other than the Postoffice was likely to damage their revenue. There was a feeling now at the Postoffice, for which he thought there was some justification, that if a telephone service was properly worked in close communication with the Postoffice, so far from damaging the telegraph service it might actually assist it.

The motion was then negatived without a division.

Disclaimer in Firman Patent.

Among the announcements made in the Official Gazette of the United States Patent Office of April 12th, the following item of interest to telephone men appeared under the head of "Disclaimers:"

252,576.—LEROY B. FIRMAN, Chicago, Ill. IMPROVEMENT IN MULTIPLE SWITCHBOARDS FOR TELEPHONE EXCHANGES. Patent dated January 17, 1882. Disclaimer filed April 8, 1898, by the present assignee, the Western Electric Company, Chicago, Ill.

Enters its disclaimer:

"To the said second claim in the specification of the said letters patent, which is in the words following, to wit:

"2. The combination of two or more multiple boards to which the lines of the terminal stations are connected, and means, as described, whereby the switchman may readily ascertain what lines are in use."

Enclosed Arc Lamp.

A modification of the enclosed arc lamp has recently been perfected by the General Electric company, which, while preserving the essential features of the well-known direct and alternating-current

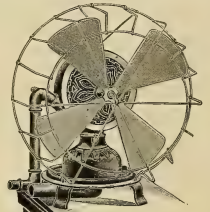
ENCLOSED ART LAMP

lamps, with enclosed arcs, substitutes a flared porcelain reflector for the outer globe. The mechanism of the lamp is similar to that of the standard enclosed arc lamps, but the use of the reflector instead of the globe allows a large amount of light, which otherwise would be absorbed in the outer globe, to be thrown down by the reflector and thus utilized. Calculating this absorption of light at from 10 to 30 per cent., the single-globe lamp allows of the utilization of just so much of the total light from the arc, as well as that which is reflected. In cases in which the direct light from the arc is not objectionable and a general diffusion of the light not absolutely desirable, such as in cafes, hotels, restaurants, etc., the single globe is peculiarly adapted.

In designing the lower part of the frame, care has been taken to render it both light and delicate and yet sufficiently rigid to withstand ordinary usage, without interfering to any extent with the passage of the light or casting heavy shadows. It is highly nickeled and thus, during the daytime when the light is not needed, the ornamental appearance of the lamp is not detracted from. The inside of the porcelain shade is highly polished and gives a good reflecting surface. It is interchangeable and can be used with globes for either direct or alternating enclosed arc lamps. By an arrangement of the lower rim of the cover of the mechanism the reflector may be substituted for the outer globe of the double-enclosed arc lamps. As in the direct-current double-globe lamps, a simple adjusting coil allows of the use of 5, 4½ or 4 amperes. By using a reflector instead of the globe a very satisfactory light may be obtained from this lamp with a current of only four amperes. A reactive coil in the alternating lamps allows of adjustment for any line voltage between 100 and 120 volts and frequencies of 60 and 125 cycles.

Triumph Water-driven Fan.

The cut represents the Triump water-driven fan, manufactured by the Specialty Manufacturing company of Indianapolis, Ind., which is especially designed for use on counters, dining tables, bedrooms and various other places where a fan is needed. This fan is run by water pressure, and it is said that a one-sixteenth-inch jet of water operates the motor at full speed. It is used with hose connections to service pipe and hose for waste, it



TRIUMPH WATER-DRIVEN FAN.

may be placed in an out-of-the-way place, and the course of the breeze may be directed at will. These fans are so simple in construction that anyone who can screw a hose coupling on an ordinary pipe or faucet can attach them without any additional expense.

The brass nickel-plated motor is attached to a base which is ornamental and beautifully enameled. The fan complete weighs 15 pounds and measures about 15 inches from bottom of the base to the highest point. It has 12-inch blades and runs at high speed and moves an abundance of air. The Specialty Manufacturing company also manufactures water motors of various sizes for running telephone generators, sewing machines, fans, coffee mills and other small machinery.

Electric Bicycle Lamp.

The accompanying cut shows a new bicycle lamp placed on the market by the Portable Electric Light company, 1242 Marquette building.

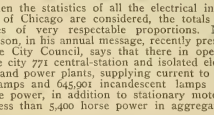
The lamp light or reflector is made entirely of brass, nickel-plated, and contains an incandescent lamp, together with an imported ground lens. The bicycle reflector can be attached to head or fork of frame as desired.

The batteries are perfectly dry and are put up in cartridge form, and when exhausted are to be replaced by new cartridges, which can be purchased in all prominent locations, ready for use at a moderate cost, thus avoiding all inconvenience of charging or cleaning, as is necessary with storage and primary batteries.

The bicycle battery is neatly enclosed in a tubular leather case and will fit any make of drop or diamond frame on the markets. These batteries with the Marquette special incandescent lamp will burn, it is claimed, fully 15 hours, the last burning hour being of equal brilliancy to the first.

Chicago's Electrical Plants.

When the statistics of all the electrical installations of Chicago are considered, the totals reach figures of very respectable proportions. Mayor Harrison, in his annual message, recently presented to the City Council, says that there in operation in the city 771 central-station and isolated electric-light and power plants, supplying current to 27,193 arc lamps and 645,901 incandescent lamps of 16 candle power, in addition to stationary motors of not less than 5,400 horse power in aggregate ca-



ELECTRIC BICYCLE LAMP.

pacity. This is exclusive of the surface and elevated railway plants, which have a combined generator capacity of at least 40,000 horse power. Undoubtedly the electrical plant actually in service in the city at the present time has a capacity of considerably over 100,000 horse power.

The mayor devotes considerable attention, in his report, to the municipal electric-light system of the city, in which he is greatly interested. He says that during the year 1897 the number of 2,000 candle power arc lamps added was 183, the greatest annual increase since 1890. The average installation cost, including underground work, was $200 a lamp. The city now operates 1,438 arc lights from its own

plants, and during this year the system will be greatly extended, an appropriation of $150,000 having been made for the purpose. The city also rents 531 lights, making the total number of street arc lamps in Chicago 1,969. These lights are placed as follows: North Side, 241; South Side, 1,116; West Side, 612.

On the important question of the cost of maintaining the municipally operated lights the mayor does not give details nor indicate the manner in which the figure given for maintenance—$90.65—is arrived at. The paragraphs of his report relating to this subject are as follows:

"The maintenance of the electric-lighting system during 1897 was on a basis of $90.65 per lamp per year. The first six months the lamps cost on an average of $46.73 each; for the second six months an average of $43.92 each. The cost per hour per lamp for the first six months was .0245; for the last six months, per lamp per hour, .0216.

"The electric-light department has been entirely reorganized; more efficient machinery installed in the stations, which for the last six months show a saving that warrants a guarantee that the electric lighting this year will not cost to exceed $83 per light per year.

"The repairs for electric-lighting maintenance by the city were discontinued on August 5th, and repairs are now made by contract. This shows a net saving in cost of $570.71 per month. All the improvements made in the electric-lighting system have been charged to the maintenance of the system, and to secure economical operation of the system it has not been necessary to expend any large sums of money.

"During the last six months of 1897 the cost of coal was nearly double what it was the preceding six months, on account of a strike of the coal miners. This additional price for coal materially increased the cost of last year's lighting, making a difference of nearly $4 per light per year. The conditions under which the new lights will be installed, and the guarantee obtained on the apparatus used in producing lights, warrant the statement that the new lights, as installed, will not exceed a cost of $75 per light per year.

"The inventoried value of the electric-light system January 1, 1898, was $797,431.11."

The city has three arc-lighting stations for street lighting and 220 miles of underground circuits.

Considering the work of the city bureau of electrical inspection, the mayor says that the reports show that there is a very rapid increase in the use of electricity for light and power. It has been found necessary to enlarge the department to properly inspect the electrical work of the city as it is being installed. The total receipt from the fees for electrical inspection in 1897 were $16,248.52 and the expenditure for the bureau of inspection was $10,-010.18, leaving a balance of $5,338.34. The number of fires during the year ascribed to electrical causes is 91 and the total loss from these fires $9,515. But one of these fires was a serious one. The loss amounting from this fire was $8,000; the remainig $1,515 of the total loss was due to 90 fires.

On the subject of the electrolysis of buried metal pipes, resulting from the use of grounded street-railway circuits, the mayor remarks that the damage is increasing, as shown by tests, and reports that the matter has been referred to the Law Department, with instructions to protect the city's interests.

Armature Construction.

In the construction of the armatures of all direct-current generators and motors built by the General Electric company especial care is had to the production of as perfect and durable a part as possible, without sacrificing any detail essential to efficiency and perfect operation. New ideas have been incorporated, and old and tried features retained. The wire, iron and copper, must reach a certain standard of excellence or be rejected; each step in construction is carefully inspected and the completed armature is subjected to a test many times more severe than the severest conditions which would be met with in actual service. Nothing is left to chance.

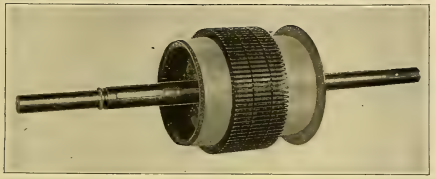


Fig. 1.

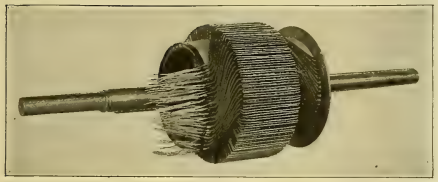

Fig. 2.

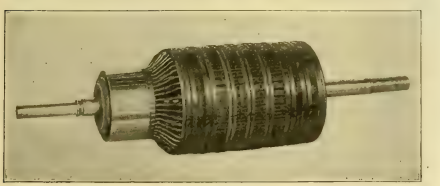

Fig. 3.

ARMATURE CONSTRUCTION

In the armatures of the new type of slow and moderate-speed direct-current generators and motors these characteristic features are strikingly apparent. The completed armature is a slotted body of barrel shape, so built that no part is susceptible to movement or vibration. There are no sharp bends to the wire over sharp metallic edges, and each coil is so laid on the core that the outer periphery of the core itself affords it complete protection from mechanical injury.

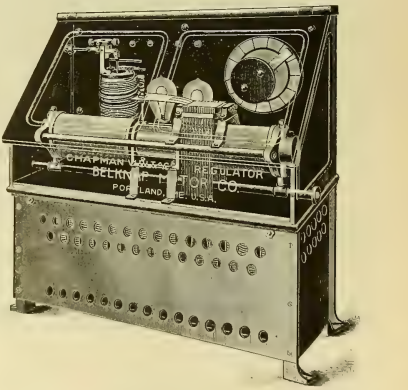
The spider castings holding the slotted sheet-iron laminations are extended into cylindrical flanges at both ends. The coils, previously shaped on a form, are laid in the slots, and the ends lie along those flanges at each end of the spider instead of being bent down sharply toward the shaft. The coils are formed and insulated before assembling on the core, in order that, before application in their final position, they may undergo a careful test, and no coil is used that does not emerge from this with insulation intact. The insulation used is similar to that employed in the General Electric railway motors, and in the operation of these it has given ample proof of its excellent qualities. It is tough, impervious to moisture and practically indestructible except under abnormal overload, while it affords high resistance to puncture, rendering injury from lightning extremely improbable. The insulated coils are laid in place in insulated slots in the core and are simply pressed home. The advantage of this method, compared with that employed on an armature with the wire wound directly upon it, is obvious.

The cylindrical winding has many positive advantages. A very large radiating surface is provided for the conductors, and this, combined with special air ducts for the passage of currents of air through the core from the interior outwards, tends to keep the armature cool; the length of wire is reduced to a minimum, and consequently the losses due to armature resistance are also reduced, while the efficiency of the machine is greatly increased. The complete coil being formed separately and then applied, any one or more coils may readily be removed and replaced.

The coils are firmly secured in the slots on the cylindrical extensions so that no part can move or vibrate. Indeed, rigidity is one of the most important advantages of the cylindrical winding, since without motion of the parts neither injury nor deterioration of the insulation is likely to occur. The ends of the coils are curved down to the commutator, and the connections are so arranged that open-circuiting is impossible. The illustrations show the three different steps in the construction of a General Electric slow and moderate-speed generator armature from the completed core (Fig. 1) to the completed armature (Fig. 3). Fig. 2 shows the method of applying the coil to the core.

New Voltage Regulator.

The new Chapman voltage regulator, manufactured by the Belknap Motor company, Portland, Me., embodies all the essential principles of the original type, but is constructed in a more simple and effective form, the working parts being reduced to a minimum and arranged for the greatest convenience of manipulation, the needs of central stations having been more carefully studied. It consists of three essential parts—a set of resistance coils to be inserted or removed from the field-magnet circuit of the generator to be regulated, a working solenoid to do the work of inserting and removing the coils from the circuit, and an auxiliary or relay solenoid to determine the movement of the working solenoid. The resistance coils are made of German silver, of a size sufficient to give ample radiating capacity for the field current of the generator for which they are constructed. They are connected to a series of copper segments placed in a horizontal row, and having a contact slider arranged to move over their surface. This contact slider is mechanically connected to the moving core of the working solenoid. The working solenoid consists of two differentially wound coils of wire placed on a brass tube, one at each end of the tube, and the whole placed in a horizontal position. The middle portion of the tube is left vacant. In side of the tube a soft iron plunger is fitted as a piston to the tube and somewhat shorter than the distance through the two coils; at the center portion of plunger a rod is attached which passes out through a longitudinal slot cut in the vacant portion of the tube. The contact slider above described is attached to this rod and so moves with it and with the iron plunger. In order to prevent too quick a movement of the plunger a simple and ingenious retarding device is used, in which the moving iron plunger is made to serve as a dash-pot. From one end of the brass tube to the other a small pipe is connected, having a hand valve in it, to regulate the flow of oil. The two



NEW VOLTAGE REGULATOR.

ends of the brass tube, together with its connecting pipe, are completely filled with oil and closed up tight. The movement of the iron plunger toward either end can then take place only as it displaces this oil and causes it to move through the pipe and to the other end, and the rapidity of this movement can be very finely adjusted by means of the valve above described.

The force tending to move the iron plunger is the difference between the attractions of the two end coils, and this balance is maintained or upset by the action of the small auxiliary solenoid, whose only work is to cause one or another of the two platinum-pointed screws to make contact with the brass lever supporting its core. Contact with one screw causes perfect neutralization of the differential coil at one end of the working solenoid and so disturbs the balance and causes the plunger to move toward the other coil, and contact with the other screw causes neutralization of the coil at the other end and a movement in the other direction. The small solenoid may be wound to suit a variety of purposes, any one of which may be required in station regulation. It may be wound with a simple fine winding to be connected as a shunt across the lines to be regulated, and in this case it will secure constant potential regulation at the point of attachment to the line. Or it may be wound with a fine winding connected as a shunt to the line and a coarse winding in series with the line, in which case it will regulate for constant potential at some distant point which may be predetermined by the setting of an adjustable compounding switch provided as a part of the regulator. Or the small solenoid may be wound with a single coarse wire placed in series with the line; in this latter case it will secure regulation for constant current in the lines. But whatever be the nature of the regulation the small solenoid will perform its duties with an accuracy as close as one per cent above or below the normal, and is adapted to either direct or alternating currents.

Alternating currents are especially capable of close regulation by this instrument, as the slight jar incident to their flow through the small solenoid almost entirely eliminates the element of friction at the pivots of the lever supporting the core, and it will easily recognize a change of one half of a volt on a 110 volt circuit. The economy of good regulation is at once apparent when it is remembered that the life of an ordinary incandescent lamp of 50 watts and 16 candle power is greatly shortened if operated at a voltage jumping at times to a few per cent. above the normal.

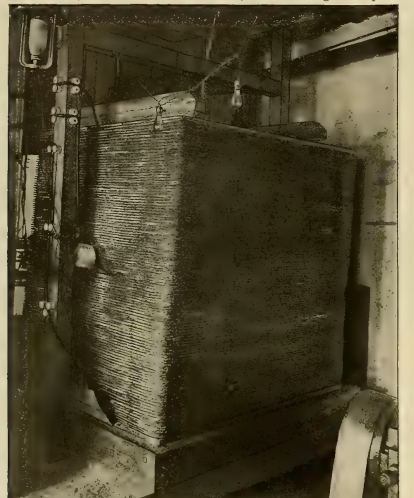
This regulator may be so applied to the regulation of a constant current as well as a constant voltage, and when used for this purpose will be found especially useful in the charging of storage batteries, as it maintains a constant current from the time the charging commences until it is completed. To accomplish this result it is only necessary to add a separate solenoid, wound with a coarse wire, a double-point switch being used to shift the apparatus from the constant voltage basis to the constant-current basis of regulation.

Remarkable High-tension Storage Battery.

Storage batteries have been constructed in a great variety of shapes embodying numerous ideas intending to increase their efficiency or their life. But what may fairly be claimed to be the most remarkable storage battery of all is that now employed in furnishing current for lighting the village of Souderton, Pa., a town of some 3,000 inhabitants, situated about 30 miles from Philadelphia.

This battery is shown in the picture. It consists of 110 lead plates, piled one above the other, each plate six feet wide by seven feet long; the total height of the battery is seven feet, and it weighs no less than 16 tons. What is particularly striking is that the plates are exposed without any enclosing tank whatever.

Before going into the details of the construction of the cell it may be well to recall that it is now several years ago that Prof. N. H. Edgerton, whose electric motor will be recalled by many engineers whose memories go back to the beginning of electric-motor work, conceived the idea that a battery could be made which would furnish any desired potential and in a form practical for every class of work. Working along this line, Prof. Edgerton's work finally crystallized into a type of battery in which each plate formed, as it were, a couple by itself, one side acting as the positive and the other as the negative in a battery, and thus, at the very outset, reducing the number of plates required one-half. The next problem was to group these plates so that they could be maintained in position to permit of the introduction of the necessary electrolyte, and to keep it in place.



REMARKABLE HIGH-TENSION STORAGE BATTERY.

In the battery illustrated each plate of the cell, excepting the one at the bottom, is coated on its under side to the depth of one-eighth of an inch with litharge. This forms the negative side of the plate. In the hollow on the top of the plate is a layer of red lead, also one-eighth of an inch in thickness, which is covered with a thin sheet of asbestos, and on this again is spread a layer of granulated oak charcoal, covered with a sheet of muslin. The plates thus prepared are piled one on top of the other, the result being that, as above stated, each plate constitutes in itself a positive and a negative, with the result that there is an electromotive force of 2.2 volts between each two contiguous plates. The electrolyte, of sulphuric acid, is syphoned in between the plates and is absorbed and held in place by the granulated charcoal.

In the Souderton battery 110 plates of this kind are piled one on top of the other, so that at the terminals there is a pressure of 220 volts. Actual measurements with a Weston voltmeter showed a difference of potential of 225 volts on open circuit, and the normal capacity of this battery is 3,000 ampere-hours.

This large cell is located in the works of the High Tension Electric Storage company, and, as stated above, furnishes current for all the public and private lighting in that town, consisting of 24 arcs and 600 incandescent lamps, the latter connected to three-wire circuits.

For the charging there are employed three dynamos, two of 40 kilowatts capacity, respectively of the Eddy and C. & C. type. One of these machines is of 250 volts and the other 500. A third machine, built by the Electro-dynamic company, is of 110 volts, and is employed as an equalizer to feed either side of the 220-volt battery which may be required to be brought up in charge equal to the other side when the two sides are unequally drawn upon. This great cell is charged at 250 amperes, but this can be raised to 2,000 for a short time without injury.

The advantage claimed for this type of a cell is that it is impossible for any of the active material to fall away from the plate, so that it constantly maintains its original capacity, while at the same time preventing short-circuiting between the plates. It is also pointed out that the current passes through from one plate of the cell to the other with absolute uniformity of density, each square inch giving out and receiving as much current as at every point on the plate, so that the action on the active material is absolutely uniform throughout. Then, again, the question of terminals is practically done away with, as there are only two terminals in the whole battery of 220 volts, one at each end plate.

While the battery just described represents the largest work of the company thus far undertaken, it is evident that there is hardly any limit to the potential which can be obtained by cells constructed in this manner. It is stated that the company is now about to undertake, on an order, the construction of a battery to deliver 1,000 volts.

It will be evident, however, that besides central-station work the battery is adapted for private plants and for portable work. Thus, among the electric-lighting plants equipped with the high-tension storage battery, is that in the Independent building at Souderton, Pa., where 20 16 candle power lamps are installed, operated from the storage battery. This battery is charged with a dynamo run by a two horse power Witte gasoline engine, which also furnishes power to run a large cylinder press and paper folder.

The company has designed a large variety of types of batteries for special work, such as for the use of physicians, batteries for lantern projection and for general uses of all kinds. High-tension battery of the type described has been in actual operation lighting an apartment house in Philadelphia during the last two years.

The works of the company are situated at Souderton, Pa., and are thoroughly equipped for carrying on the company's work. They are located directly opposite the tracks of the Reading railroad, so that the shipping facilities are of the best. The offices of the High-tension Electric Storage company are in Philadelphia. Prof. N. H. Edgerton, inventor of the battery, is president of the company, and the following-named gentlemen are the officers: Dr. Joseph H. Wilson, vice-president; A. M. Gissinger, secretary; J. K. Clenner, treasurer; J. B. Alderfer, general manager.

National Electric Light Convention, Chicago, June 7th, 8th and 9th.

The most popular line from Cincinnati, Louisville and all points South to Chicago is the Big Four Route via Indianapolis; magnificent sleeping cars and unequaled dining-car service. For maps, rates, etc., address E. O. McCormick, passenger traffic manager, Big Four Route, Cincinnati, O.

CORRESPONDENCE.

New York Notes.

New York, April 18.—Much regret is expressed in electrical circles at the failure of Alfred Dolge & Son of Dolgeville, N. Y., last week. Surprise was created by the application for a receiver for the firm, as Mr. Dolge's large enterprises were thought to be in good shape. The nominal value of the assets is placed at $1,150,000, but the liabilities are about $1,400,000. Mr. Dolge was engaged in the manufacture of felt products and in several other enterprises. His principal object in life was the building up of the village bearing his name, which was considered a thriving manufacturing town. About 2,500 persons are dependent on the Dolge enterprises for a livelihood. Alfred Dolge was one of the pioneers in the utilization of electric power for manufacturing industries, and the second Edison dynamo was purchased by him. The water power was transferred into electric energy to run his mills, and then he began plans for the construction of power development on a larger scale. He purchased 40,000 acres of virgin Adirondack forests, in which are located several lakes. Then the Dolgeville Electric Light and Power company was formed, and the line was extended to Little Falls. The plant is capable of producing 4,000 horse power, and exports say that it can be increased to 12,000 horse power. This electric power Mr. Dolge designed to furnish the towns throughout the Mohawk Valley.

A majority of the stockholders of the Kings County Traction company have voted in favor of dissolving the company. The directors, it is said, will proceed to wind up the affairs of the company, dispose of the assets, and, after paying the debts of the company, divide the balance among the

stockholders. It is likely, however, that this step will not be taken without a strong fight by the dissenting stockholders, who, it is understood, have asked the attorney-general of the state for an investigation.

It is probable that the familiar steam-railroad cars on the Brooklyn bridge will be withdrawn from service as soon as the elevated railroad companies begin operating over the bridge, thus effecting a saving of $50,000 a month in the running expenses. Superintendent Martin says that with the "L" trains and trolley cars both in operation the bridge railroad could be abandoned. He believes that the revenue derived from the railroad companies for their exclusive privileges would be ample to maintain the bridge. Commissioner Shea will soon have a conference with the railroad officials in relation to fixing the tolls. At present the trolley companies pay five cents per car per round trip, and Mr. Shea regards this amount as entirely too small. He expects the companies to be willing to come to an agreement with the city without any litigation.

John H. Starin, one of the Rapid Transit commissioners, left the city for Europe on Saturday. Members of the commission say that Mr. Starin's trip at this time involves no inconvenience, especially as it is probable that he will stay abroad only a short time. The commission will have practically no business of importance to transact for a month at least. It will take no action toward awarding the contract for the underground road until the time allowed to the Manhattan Elevated Railroad company to consider the advisability of accepting or rejecting the franchises offered it to it has elapsed. Again, the commission cannot proceed with the contract until a reasonable time has been allowed to Corporation Counsel Whalen to pass upon it, and it is assumed that Mr. Whalen, following the policy of the administration, will withhold his judgment as long as possible.

Mr. Samuel Insull, president of the National Electric Light association and of the Association of Edison Illuminating Companies was in New York last week. He takes a lively interest in the progress of the electrical exhibition and has informed the management that he will take the utmost pleasure in coming on especially from Chicago, in behalf of those two associations or bodies, to participate in the opening exercises on May 2d. These exercises as now arranged promise to be of an unusually striking and interesting character. The preparations for the event are proceeding with unabated vigor. Arrangements have been made for the meetings of about 50 associations of stationary engineers. These associations will come from New York, New Jersey, Pennsylvania, Massachusetts, Rhode Island and Connecticut. Several rooms suitable for meetings have been provided, and the various lodges invited, almost without exception, have accepted the invitation and will hold their meetings there on their regular meeting night as the guests of the Exhibition company. W. F. O.

PERSONAL.

T. W. Ness, representing the Holtzer-Cabot Electric company of Boston, visited Chicago electrical men this week.

J. S. Daily, manager of the Chillicothe (Ill.) Water, Electric Light and Power company, was a Chicago visitor last week.

William Goltz, the well-known electrical man of Milwaukee, has connected himself with the firm of Meysenburg & Badt of Chicago in the capacity of secretary.

W. R. Mason, the representative of the Walker company in St. Louis, was in Chicago on Monday visiting friends. He reports a fair outlook for business in St. Louis.

Edward R. Knowles, the well-known electrical engineer of New York, has accepted the position of superintendent of the power motor department of the Sprague Electric company.

J. F. Stevens of Philadelphia was among the out-of-town electrical men who have been visiting Chicago recently. Mr. Stevens represents the Keystone Electrical Instrument company.

Mr. N. G. Harvey has resigned his position with the Gould & Eberhardt company to accept the management of the house-goods department of the Illinois Electric company of Chicago. Mr. Harvey has been in the business a number of years and has many friends in the electrical fraternity.

ELECTRIC LIGHTING.

The contract for four water-tube boilers of a nominal capacity of 500 horse-power each for the new street are lighting-plants of the city of Chicago has been awarded to the Aultman & Taylor Machine company of Mansfield, Ohio, for $67,800. One boiler will be placed in the Fourteenth street station, another at the new plant at Rice and Lincoln streets, and the others in new plants that have not been definitely located.

ELECTRIC RAILWAYS.

Recently the last horse car was taken off the streets of Budapest. The surface lines have been converted into an electric system, while the Budapest underground railway also has electric traction for a distance of 53 miles. Plans for an extensive system of electric elevated and underground railways have just been made public and received with general approval. At the present time Budapest is the only large town in Europe in which the horse car has been banished entirely from the streets.

The Main street inclined plane and Mount Auburn electric line in Cincinnati, Ohio, over which there has been much litigation, were sold at auction on April 14th by order of the United States court. The property as a whole was bought in by the Cincinnati Consolidated Street Railway company for $278,000. Many street-railway men attended the sale.

Work on the Cicero and Harlem extension of the Lake Street elevated railroad of Chicago, from the terminus of the line at Fifty-second avenue westward, has been begun. The time allowed for the completion of the work expires on September 15th, but as the iron for the superstructure cannot be delivered so soon the town board will be asked for and will probably grant an extension of 60 days.

Superintendent Nagle of the Chicago City Railway company applied to the mayor last week for permission to string trolley wires in State street between Van Buren and Randolph streets, to complete the system of temporary down-town trolley loop. The mayor refused the application. He says that under no circumstances will he allow the stringing of trolley wires in State street north of Van Buren street.

ELECTRICAL SECURITIES.

A concern entitled the Standard Electric Magnetic Power company has been chartered with a capital of $5,000,000 to operate a plant at Martinsburg, W. Va.

The Columbus Street Railroad company reports gross earnings for March of $51,729, an increase of $4,062 as compared with the same month of last year, and net $27,231, an increase of $5,328.

Directors of the Edison Electric Illuminating company of Boston have declared the regular quarterly dividend of 1¾ per cent., payable May 2d. Books will close April 15th and reopen May 3d.

The Sprague Electric company of New York has declared a dividend of three per cent. upon the preferred stock, payable May 2d to stockholders of record April 18th. The organization was incorporated last October with an authorized capital of $5,000,000, of which $2,500,000 is six per cent. preferred.

The North Chicago Street Railway company will increase the capital stock by 20 per cent., from $6,600,000 to $7,920,000, to take up debentures and wipe out debts incurred for extensions and betterments and the substitution of electricity for animal power. The authorized capital stock of the company is $10,000,000.

On the acquisition of the People's electric street railway of Amesburg, Mass., by the Lowell, Lawrence and Haverhill Electric Street Railway company, the managers of the latter company approved the issue of five per cent. first-mortgage bonds amounting to $65,000, the proceeds to be used in retiring the outstanding capital stock of the People's company, on a basis of one bond for 10 shares of stock.

Efforts are being made to reorganize the Pennsylvania Traction system, which has been in the hands of a receiver for nearly two years. William B. Given is said to have secured $550,000 of the $600,000 bonds issued on the Lancaster city lines, and has also purchased two-thirds of the bonds secured on the Columbia and Ironville and Donegal roads. Negotiations are pending for the Lancaster and Columbia line. It is said that the Provident Life and Trust company of Philadelphia is behind the deal, and that several financiers and business men of Lancaster will coöperate in the new organization.

MISCELLANEOUS.

The Treasury Department is inviting sealed proposals until April 26th for installing an electric light and power plant in the United States courthouse and postoffice building at Louisville, Ky. Specifications and plans can be obtained upon application to O. L. Spaulding, assistant secretary of the treasury, Washington, D. C.

TRADE NEWS.

The Electric Exhibition company of New York has practically completed all arrangements for the opening of the exhibition on May 2nd. It has moved its headquarters from 15 Cortlandt street to Madison Square Garden, where the executive office of this company will be hereafter located.

The Sprague Electric company has issued two attractive catalogues relating to its Lundell motors. One, on "Electric Motors in the Art of Printing," is especially artistic and well printed. The other describes the '98 models of the Lundell fan motors and is also a handsome catalogue. Both will be valuable aids to purchasers.

The D. A. Kusel Telephone and Electric Manufacturing company of St. Louis has found it necessary to move to larger quarters, owing to the constantly increasing demand for its well-known products. The company is now located at 1105 Pine street, and is in a better position to-day to fill orders than at any time heretofore. The company states that it has just closed a contract for an exchange at Muscogee, Indian Territory, for a 125-drop switchboard and 75 telephones.

The new catalogues of the Diamond Rubber company of Akron, Ohio, show a fine line of mechanical rubber goods, such as belting, hose, packing, wheel tires, etc., and also of small metal fittings, as couplings, nipples, reels, nozzles and the like. It is announced that the organization of the company is now centered in the president, Walter B. Hardy, who is stated to possess an intimate knowledge of the needs of the trade and also the skill and experience necessary to supply them.

The Central Electric company of Chicago is now furnishing the celebrated Manson tape put up in neat tin boxes, holding one-half pound each. This innovation will be readily appreciated by the many users of his product, as it preserves the tape in a fresh condition and also prevents filings and the many particles of metal always found in a "kit" or on a bench from adhering to the tape and destroying its effectiveness. The company is carrying in stock a full and complete line of the celebrated McIntyre connectors, as well as the various tools used in connection therewith.

The Jersey Electric company of 744 Broad street, Newark, N. J., a concern recently organized to extensively operate in the renewing of incandescent lights. It has been particularly careful to get experienced help in this line of bousiness, so that the production may be superior to any renewed lamp manufactured. Mr. Harry Gregory, who has been elected treasurer and general manger, is a gentleman well known in the electrical business, and is ably assisted by Mr. Thomas G. Westcott as general sales agent. It is the new company's idea to locate agencies in different portions of the country. It now has a standing cash offer for incandescent lamps that have been cast aside.

The electrical trade will be interested to know that the American Electric Fuse company is now installed in a new and spacious factory in Chicago at 521 to 531 Wabash avenue. For over a year the company has felt the need of more commodious quarters, owing to the phenomenal increase in its business. It has been holding itself almost exclusively to the production of electric fuses and wire connectors in addition to selling other supplies, but, owing to the popularity of the company's goods, especially among the telephone and telegraph people, the old quarters were found entirely inadequate to take care of the greatly increased business. The present quarters on Wabash avenue place the company in a position to take care of the greatly increased amount of business. A special fuse-wire machine designed Mr. Masstadt of the company has just been installed. This machine turns out an immense amount of fuse wire in a day and places the company in a position to fill all demands.

BUSINESS.

The Western Electric company announces that it has the exclusive agency for the Sprague Electric company's conduit and has in stock in Chicago a large and complete supply of interior conduit of all sizes, upon which it is prepared to quote the lowest prices.

The Ball Engine company, Erie, Pa., which builds engines exclusively for electrical purposes, is reported to be crowded with work. The good reputation of the Ball engine built by this company has, of course, much to do with the satisfactory condition of its order book.

The Farr Telephone and Construction Supply company, 357 Dearborn street, Chicago, is meeting with flattering success, and is doing a large business to-day than ever before. The company desires to place in the hands of every telephone user a copy of its catalogue, which contains valuable information for telephone users.

Queen & Co. of Philadelphia present in a new circular a description of their Queen-Acme portable testing set. Their claims on this instrument as to range and accuracy of measurement are very wide. The testimonials in the new circular suggest that the set is widely used, both in this country and abroad. This descriptive pamphlet will be sent on application to those interested.

The Berlin Iron Bridge company of East Berlin, Conn., has just completed at Grand avenue, New Haven, Conn., a steel bridge 427 feet in length, 52 feet in width, with one roadway and two sidewalks. The approaches on the bridge consist of two deck plate-girders. The draw span is 200 feet in length and is operated by electricity, which is employed for lighting the bridge by night. The bridge is to very heavy construction, the roadway being paved with vitrified brick adapted to heavy city traffic.

The Central Electric company of Chicago is active and energetic as ever in the pursuit of business. It has issued a little circular on "Tape Talk," relating to the familiar Okonite product. It claims that its stock of house goods is the most complete stock of the kind and says that increased orders in this department give evidence of the popularity of large stock and favorable prices. Attention is also called to the fact that the Central can

ries in stock all sorts of electrical heating and cooking utensils.

Probably one of the most useful and interesting books on insulation ever issued is now being mailed to the electric street railways and electrical manufacturers throughout the country by the Mica Insulator company of New York and Chicago. The book is made up so that each page of reading matter, aside from the title and index pages, is descriptive of the "sample of insulation" preceding it. The company will be pleased to mail upon application to those who are users of high-grade insulators a copy of this manual, and also calls attention to the fact that its materials are carried in stock both at New York and Chicago.

Broomell, Schmidt & Co. of York, Pa., manufacturers of the American fuel economizer, report that they have more business in sight at present than at any time during the past year. Their shops are running to their full capacity to keep abreast of orders. They are now at work on an installation of their apparatus for the Gardner Electric Light company of Gardner, Mass., and they are also completing the installation of seven economizers for the Arbuckle Sugar Refining company of Brooklyn. This apparatus will take care of the gases from boilers to the capacity of 4,800 horse power. The American economizer will be seen on exhibition at Madison Square Garden, New York, in May, as the firm has arranged for a working exhibit to be shown at that time

The Mason Telephone Pay Station company of Ludington, Mich., is now manufacturing automatic telephone pay stations especially for the independent field. These instruments, which were described in the Western Electrician of March 5, 1898, have been on the market for some time and a large number are now in use. It is claimed that they are giving entire satisfaction, as they are thoroughly reliable and fully guaranteed by the manufacturers. The Mason company is willing to ship one of these instruments on 30 days' trial to any responsible telephone company, and if not found satisfactory, it may be returned at the expense of the Mason company. It is suggested that independent telephone men who contemplate the use of automatic pay stations write the Mason company for descriptive catalogue and further particulars.

From all reports the Electrical Exchange of Chicago is doing an excellent and rapidly increasing business. The exchange has just shipped to the Alaska Transportation and Mining association of St. Michaels a complete electric-light plant, to be used on one of the company's steamboats running on the Yukon River. President T. S. Lane of the exchange states that his institution has also just secured the agency for the Upton Midget arc lamp, and that one of these lights will ornament the bow of the steamboat that plies up and down the Yukon. Incidentally it may be said that the Electrical Exchange has, particularly during the last week, done a remarkably fine business, complete electric-light plants having been sold to Shawneetown, Ill., and Dodgeville, Wis.

A very large amount of arc apparatus in the local electric-light stations of the country is being exchanged for new arc dynamos of more modern design and larger units. Many of the largest electric arc-light stations in the country have exchanged their small 25, 40, 50 and 60-light dynamos for modern arc dynamos of 100-lights capacity and upwards. The possibilities of operating an arc-light station more economically by such changes are very great. As an example the Virginia Electric company, a new corporation of Norfolk, Va., which is a consolidation of two competing electric-light companies, has just made a contract with the Brush Electric company by which the latter company takes in exchange for a modern equipment the following apparatus: Six 40-light and one 30-light Brush dynamos, five 50-light and one 30-light Thomson-Houston arc dynamos and three 50-light American arc dynamos, a total of 16 arc dynamos, with a very low efficiency as compared with the present machines; requiring 16 belts, 16 pulleys, 32 bearings, 32 oil-cups and a large amount of floor space which could be used to advantage for an increase of business, without mentioning the extra labor and attention required for the operation of these old dynamos. In place of these old machines the Virginia Electric company will now use only six 120-light 1,200 candle power Brush arc dynamos with an efficiency of at least 15 per cent. greater than the old dynamos and a corresponding amount of saving in coal, with self-oiling bearings requiring little if any attention and with a greater capacity in the number of lights. The voltage on the circuits with the old dynamos has not exceeded 2,500, while one of the large dynamos is rated at 6,000 volts, but with the use of the multi-circuit system of the Brush company there will be no change in the voltage on each circuit and no change whatever in the rearrangement of the lamps or the circuits themselves. Three circuits will be run from each dynamo to an 18-circuit switchboard, to which will be attached the old circuits exactly in their present condition. The advantage of the multi-circuit system is very great in such a case, because it does not necessitate a large expenditure, and the overhauling, rearrangement and practical rebuilding of the lines for a high voltage.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued April 12, 1898

602,142. Supply System for Electric Railways. Percival J. Pringle, London, England. Application filed October 27, 1896. Patented in England February 2, 1894.

A system of electric traction is proposed consisting of the combination of a rail forming the return circuit, an electrically propelled vehicle on the track having collectors attached which pick up the current from a series of surface plates or rails, a certain number of which form a block, and a shunt collector on the vehicle connected to the return rail through a resistance also carried on the vehicle, a main supply conductor from the source of electricity and conductors from distributers to the separate sections of a block, a series of distributers, one for each block of sections for successively connecting the current from the main supply to the separate sections in exact relationship with the movement of the car or vehicle.

602,172. Secondary Battery. Friedrich W. Schneider, Triberg, Germany. Application filed June 10, 1897.

The supporting frame consists of parallel perforated plates with the spacing tubes and connecting bolts, and the electrodes consist of perforated tubes containing active material, the tubes being piled in the spaces between the plates and resting upon the spacing tubes.

602,174. Telephone Transmitter. Herbert E. Shreeve, Boston, Mass. Application filed August 26, 1897.

This transmitter employs a vibratory diaphragm, front and back electrodes mounted thereon, the former being rigidly and the latter elastically attached thereto; with a variable resistance medium composed of substantially spherical or rounded carbon granules or particles, held between and in constant contact with the electrodes.

NO. 602,235.

602,176. Storage Battery. George A. Washburn, Cleveland, Ohio. Application filed May 22, 1897.

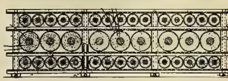
A storage battery electrode has on each side a series of groups of concentric ring-shaped projections of substantially uniform cross-section one with the other and equally spaced at all points to hold active material between them and standing out above the adjacent surface of the plate, and a hole centrally through each group communicating with the opposite side of the plate.

602,182. Dynamo for Electric Car-lighting Systems. Edwin J. Preston and Arthur B. Gill, London, England. Application filed February 25, 1895. Patented in England March 17, 1894, and November 25, 1895; in France January 17, 1895; in Belgium January 17, 1895; in Germany January 19, 1895; in Switzerland February 5, 1895; in Italy March 31, 1895; in Brazil April 24, 1895; in Austria April 30, 1895; in Canada October 3, 1895; in Hungary November 3, 1895; in Victoria December 7, 1895, and in India December 27, 1895.

The arrangement provides for a dynamo in one-sided suspension from the under side of the vehicle, with pulley-and-belt connection between the shaft of the dynamo and one of the vehicle axles, the belt being in about a horizontal direction, the dynamo acting as a tension device for the belt, and means for shifting the point of suspension of the dynamo and thereby altering the tension of the belt.

602,208. Electric Block System. Franz Burger, Fort Wayne, Ind. Application filed August 2, 1897.

With the leading and return conductors there are a series of insulated trolley sections, a series of section feeders, a normally closed switch for each section feeder located at the entrance of each trolley section and adapted to be engaged by the trolley, a connection between the switch and a rear trolley section, and a switch-operating magnet in the connection whereby when a car enters a section the corresponding magnet is energized to open the switch and break the circuit controlling the rear section, and when the trolley leaves the section and enters a succeeding section, the trolley operates the switch to restore it to its normal or closed position.



NO. 602,172.

602,212. Process of and Apparatus for Electro-depositing. Emile L. Dessolle, Epinay sur Seine, France. Application filed August 25, 1897.

The process consists in first saturating the surface of a cathode which is of metal capable of occluding hydrogen with hydrogen, electro-coating the cathode with metal, and then stripping the deposit from the cathode.

602,218. Electric Transformer. Ludwig Gutmann, Pittsburg, Pa. Application filed October 31, 1890.

A core element for electric transformers consisting of a plate of magnetic material, two recesses or more provided in the plate for locating the transformer windings, polar projections caused by the recesses, and a second plate or strip of magnetic material interlocking with the polar projections of the plate named first.

602,235. Electric Cord-adjusting Device. Francis N. Lawton, Summit, N. J. Application filed April 5, 1897.

An adjusting device for flexible insulated conducting cords consisting of a metal wire, rod or form of metal having a smooth curved exterior surface, bent or crimped into a series of successive loops arranged in the same plane, has a layer or coating of insulating vitreous enamel thereon.

NO. 602,208

602,239. Aerial Railway. Martin A. de Palacio, Madrid, Spain. Application filed December 20, 1897. Patented in Spain July 6, 1895; in France August 22, 1895; in Belgium August 22, 1895; in Switzerland August 22, 1895; in Germany August 26, 1895, and in Sweden September 19, 1895.

An aerial railway is constructed with a line of rails of U form spliced end to end, a rack located in the throat of the U of the rail, one or more suspension cables, means for suspending the line of rails from the cables, and pillars for supporting at intervals the suspension cables and the line of rails which take between the pillars their respective curves of equilibrium.

602,302. Suspending Batteries on Carriages. Reginald T. D. Brougham and Walter C. Bersey, London, England. Application filed December 13, 1897.

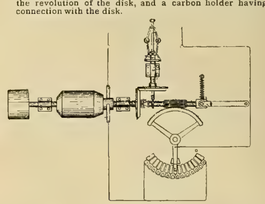
The combination of the carriage frame, a box, springs suspending the box from the frame and a rod pivoted at one end to the frame and at the other to the box, comprises one of the claims set forth.

602,325. System of Electrical Propulsion for Vessels. Jean J. Heilmann, Paris, France. Application filed December 3, 1895. Patented in Italy January 28, 1895; in India April 6, 1895; in Russia April 29, 1895; in Spain July 1, 1895; in Portugal July 19, 1895, and in Belgium October 22, 1895.

A steam engine drives two or more generating dynamos, having their armatures connected in multiple with the main conductors. There is a separately driven constant-potential exciting dynamo with which the field coils of the main dynamos are connected in multiple; a rheostat is in series with the exciter armature for varying the field strength of the dynamos; two or more electric motors are connected to the propeller shaft, having their field coils in series multiple with their armatures, and a reversing switch between the field coils and the armatures of the motors.

602,380. Electric Arc Lamp. Edgard Weber, Paris, France. Application filed September 11, 1897. Patented in France April 30, 1897 and in Austria July 6, 1897.

One claim covers the combination with a frame of an electro-magnet, a magnetic disk in the field of the magnet, a brake for the disk, an armature coacting with the magnet and controlling the brake, the magnet serving to retard the revolution of the disk, and a carbon holder having connection with the disk.



NO. 602,413.

602,404. Electric Arc Lamp. John Mueller, Cleveland, Ohio. Application filed August 27, 1897.

There is but one claim, which is as follows: In an arc lamp the combination with the carbon-holding devices and a feeding clamp having sliding engagement with the upper carbon holder, of a lifting lever adapted to engage and lift said clamp, a spring acting on said lever to cause it to engage said clamp, a cross lever pivoted on the lamp frame, auxiliary levers and thermo-expansive strips connecting the auxiliary levers respectively with the cross lever and the lifting lever, and with the cross lever and a binding post to which the main circuit is connected.

602,413. Automatic Device for Removing Resistance in Starting Electric Motors. George H. Whittingham, Baltimore, Md. Application filed September 9, 1897.

A resistance is included in the motor circuit normally or when at rest; a toothed resistance arm in engagement with the resistance; means are adapted to engage the toothed arm when starting the motor but disengaged therefrom when the motor is not running; a centrifugal governor serving to effect the engagement at the time of starting the motor, whereby the resistance is cut out; and means for returning the resistance arm to the point of greatest resistance when stopping the motor.

Western Electrician.

EVERY SATURDAY.

Vol. XXII. CHICAGO, APRIL 30, 1898. No. 18

Induction Motors in the Deering Works.

To see the largest and most interesting installation of induction motors in or near Chicago one must take a trip to the extensive works of the Deering Harvester company. If the visitor secures the necessary pass at the office, he may proceed among the yards and shops until he comes to the new twine mill, where he will find the object of his search. The stranger will be impressed with the size and activity of the works as he passes through them, and when he is told that over 5,000 men are employed in a plant covering 62 acres of ground he can readily believe the assertion. The works extend along the North Branch of the Chicago River, between Fullerton avenue and Diversey street, and transportation facilities are afforded by the Chicago, Milwaukee and St. Paul and Northwestern railroads and the river. There is also an intramural standard-gauge electric freight railway operated with double trolleys on a 220-volt all-metallic circuit. The product of the factories is the well-known Deering agricultural machinery and binder twine, and it is claimed that 14,000 carloads of raw material or finished product are yearly shipped in and out of the plant. Power for machine driving is generated in several large steam-engine plants scattered about the factories. An interesting feature of the shops is the extent to which labor-saving machines have been developed; the visitor is attracted by automatic devices of one sort or another at almost every turn. There are two steam-driven electric-light and power plants of large size. The newer one has been in operation about two months and forms the subject of this article. It is to be noted that the works are being constantly improved; they represent the growth and accretion of years; and as it is evident that the centralization of all power-generating units in one plant, with electrical transmission to the points of consumption, would result in marked economy of operation, it may be hoped that the improvement, too, is in contemplation.

The new electrical plant consists of a large three-phase generator which supplies current to incandescent lamps and a number of induction motors. It is a part of the equipment of the power house at the twine factory. This factory, with the new addition, is a very large one, turning out, it is said, over 30 miles of twine a minute. The twine is spun from manila and sisal fibers and wound into balls, which are packed in bales for shipment. The manila comes from the Phillipine Islands and the sisal is imported from Mexico and Central America. George L. Rice is the superintendent of this factory, and he takes an intelligent interest in the efficiency of the electric drive.

Only a portion of the machinery in the twine factory is operated by the motors; the greater part is driven by direct belting and shafting from the great 2,000 horse power Corliss engine, which was the most conspicuous feature of the power house of the Intramural railway at the World's Fair. This engine was sold to the Deering company after the exposition and remodeled for belt driving.

The engine-dynamo which supplies the current for the three-phase electrical plant is shown in Fig. 1. The engine is of the cross-compound condensing type, with Corliss valve gear, and was built by the Allis company. Its dimensions are: Stroke, 48 inches; cylinders, 24 and 50 inches. It is rated at about 1,100 horse power. Directly connected to this engine, as shown in the picture, is a General Electric three-phase alternator. This generator is a 600-volt, 40-cycle, 750-kilowatt machine. It has 48 poles and is operated at 100 revolutions a minute. The field magnets are revolved within the armature, which is the stationary part. A 15 kilowatt, 125-volt exciter is belted to the main engine shaft on the side of the flywheel away from the spectator in the picture.

Blue Vermont marble is used for the handsome switchboard, which is shown at some distance and rather indistinctly in Fig. 1. This board is made up of eight panels—one for the generator and seven for motor feeders—on the principle of a railway switchboard. The number of motor panels is characteristic of the thoroughness and carefulness which is shown throughout in the construction of this plant. Each motor or group of motors, as the case may be, in the factory or in the adjacent warehouse or foundry, is wired on a distinct circuit from the board and can be, and often is, started up directly from the engine room. The possibility of doing this also shows the advantage of the absence of external resistance in starting the motors. Beside the necessary switches, the generator panel is equipped with the General Electric inclined-coil measuring instruments and I-T-E circuit breakers, while the feeder panels have each a Thomson recording wattmeter and an outfit of aluminum fuses. These fuses are used because so little material is needed to carry the current. When they "blow"

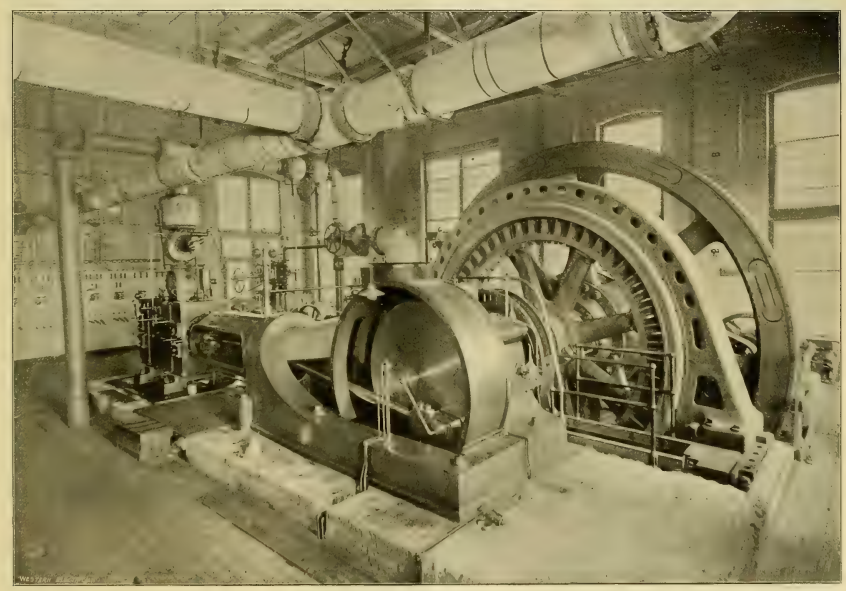


FIG. 1. INDUCTION MOTORS IN THE DEERING WORKS—THREE-PHASE GENERATING PLANT.

they are dissipated into powder; there is a puff and the fuse is gone without a mass of melted metal.

In Fig 2 on the next page is illustrated one of the side walls of the new part of the twine factory, showing the wiring from the three-phase plant and a bank of three transformers. The transformers, it should be understood, are used only in the lighting circuits; the motors are operated at the generator voltage. The stack shown at the left in this picture is that of the power plant of the twine mill.

The transmission lines are all aerial and are comparatively short for alternating systems of transmission, the greater part of the power being consumed within a radius of 1,000 feet of the generating plant; however, a comparatively small amount of current is transmitted to the lower end of the factory yards, something over one half mile distant. The larger portion of the feeders are run on the delta or triangular form of construction, thereby carrying a theoretical feature into actual practice, making the three-phase wires as nearly equidistant as possible. This was done in order to give the lines the benefit of any reduced inductive effect that might accrue from such a formation. Stranded flexible cables are used, not only as tending to make preferable con

struction, but to again react on the inductive effect of the alternating transmission.

As the greater part of the load on the generator is induction motors with the remainder in incandescent lights, the question of regulation as affecting the lighting system was a problem of much interest. In order that the variation in lamp voltage should be reduced to a minimum under changes of motor load (although the engine regulation is very close) the twine mill proper was wired on

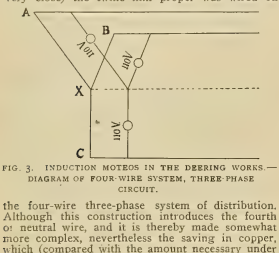

FIG. 3. INDUCTION MOTEOS IN THE DEERING WORKS.—DIAGRAM OF FOUR-WIRE SYSTEM, THREE-PHASE CIRCUIT.

the four-wire three-phase system of distribution. Although this construction introduces the fourth or neutral wire, and it is thereby made somewhat more complex, nevertheless the saving in copper, which (compared with the amount necessary under similar conditions for two-wire direct or single-phase alternating) is as 1-3 to 1, and the balance thus obtained more than compensates for the extra construction. Very little effect in lamp voltage is noticeable under sudden and varying changes of motor load. The ratio of conversion for incandescent lighting is 600 to 110 volts.

The four-wire three-phase system of distribution is illustrated by the star diagram (Fig. 3). A, B and C are the main three-phase lines and X the fourth or neutral wire. While motors of the proper

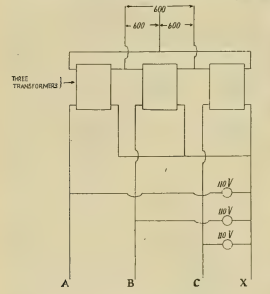

FIG 4 INDUCTION MOTORS IN THE DEERING WORKS — TRANSFORMER CONNECTIONS FOR LIGHTING CIRCUITS.

voltage could be used directly from this system, connected to the three main lines, this distribution is left to the lighting alone. Fig. 4 is a diagram of the transformer connections as actually made to carry out the scheme. The delta formation is used on the primaries and the star or "Y" formation on the secondaries. The lighting distribution is so arranged that in case of emergency, or when the three-phase power generator is shut down, power for lighting can be delivered from the single-phase alternating system of the company's old power sta-

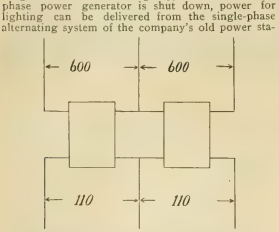

FIG 5. INDUCTION MOTORS IN THE DEERING WORKS.—TRANSFORMER CONNECTIONS FOR LIGHTING CIRCUITS.

tion over the entire network of the mills. For emergency work, repairs and the like, a 110-volt direct-current Edison dynamo can be thrown on to the system if desired. This arrangement necessitates, for the sake of flexibility and the surety of light under all conditions, that the neutral or X wire be increased in size to conform with two-wire direct or single-phase alternating conditions.

In other buildings lighted from the three-phase plant two transformers are connected as shown diagrammatically in Fig. 5, and the Edison three-wire distribution carried out on the secondaries; in other cases transformers are connected across two of the three-phase lines as in single-phase distribution.

Molding has been used on the interior wiring construction for lighting, and all cut-outs and switches are placed in asbestos-lined cabinet boxes. The interior motor circuits are open construction, and D. & W. enclosed fuses are used. The construction was planned and executed by Mr. F. L. Stevenson, the Deering company's electrician.

All motors used in this installation are of the induction type made by the General Electric company. They are ironclad, very symmetrical in design and of the best mechanical construction. They have no brushes, of course, and are started without external resistance by simply throwing a switch. They need very little attention and seem to be as effective in operation as they are beautiful in appearance. The following tabulated statement shows the number and size of motors operated from the three-phase generator:

No. of motors.	Capacity of each in H. P.	Used to Drive—
1	20	Freight elevator in warehouse.
1	30	Freight elevator in warehouse.
8	75	Twine machines.
1	50	Foundry blower.
1	50	Machinery in malleable iron-works.
1	75	Machinery in malleable iron-works.
1	50	Machinery in cutter-bar department.

In addition another 75 horse power motor has just been ordered, but not set up. This makes a total of 15 motors, having an aggregate capacity of 950 horse power. All of these motors are in or near the twine mill, with the exception of the one in the cutter-bar department, which is over half-a-mile away.

Two of the 75 horse power motors are shown in Fig. 6 (page 251) attached to the wall of one of the long spinning rooms in the twine mill. There is another motor of like capacity in this room, not

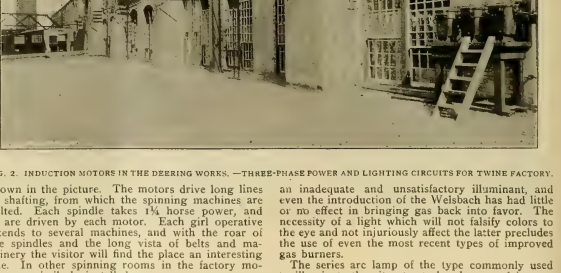

FIG. 2. INDUCTION MOTORS IN THE DEERING WORKS. —THREE-PHASE POWER AND LIGHTING CIRCUITS FOR TWINE FACTORY.

shown in the picture. The motors drive long lines of shafting, from which the spinning machines are belted. Each spindle takes 1¼ horse power, and 6c are driven by each motor. Each girl operative attends to several machines, and with the roar of the spindles and the long vista of belts and machinery the visitor will find the place an interesting one. In other spinning rooms in the factory motors are similarly installed.

The view in Fig. 7 was taken in the room where the twine is wound in balls. Two 75 horse power motors are here placed near together and fastened to the ceiling. They drive shafting from which 168 baller spindles are operated. This picture shows also the open wiring of the motor circuits and the iron box at the bottom of the service board containing the oil-immersed switch. With these switches, enclosed fuses and brushless motors, it is impossible to draw a spark in any part of the motor plant. This is of the highest importance in a factory like this twine mill, full of inflammable material. Indeed, the fact that they had no brushes, commutators or sparks was one of the greatest recommendations of the induction motors for the Deering company's use. Every precaution is taken against fire in all parts of the building, and it is felt that there is no danger from the electrical plant.

Several of the motors are used to drive machinery outside of the twine factory, as shown by the table previously given. One of these is illustrated by Fig. 8. It is a 50 horse power machine placed on a balcony in a foundry and it drives a No. 8 Sturtevant blower at 2,200 revolutions per minute. The motor turns at 600 revolutions per minute and is belted to a jackshaft. The blower supplies the blast for two furnaces used in the foundry for malleable-iron castings.

It will be noticed that in Figs. 6, 7 and 8 the motors are attached in three different positions—from the side, from the top and at the bottom. The mechanical design of the motor allows this to be easily accomplished by adjusting the frame so that the oil feeders are in the proper position. Moreover, by introducing the armature on the one side or the other, the pulley can be had on either side. The motors have eight poles and are operated at from 550 to 600 volts. They are spoken of with enthusiasm by the men in charge of the plant, who say they need no more attention than any part of the shafting. Oilers go over the shafts once a week and they give the motors all the care they get.

About 1,900 incandescent lamps are supplied with current from the three-phase generators—1,500 in the twine mill and warehouse and 400 in the foundry. The General Electric company's type H transformers are used, and they have from 80 to 150 lights' capacity each.

The plant is operated at full load, and seems to be doing its work remarkably well. It cost the Deering company probably 20 per cent. more than a direct-current outfit would have done, but it fulfills conditions that could hardly have been met by any other system, and is considered to be well worth the additional cost.

Enclosed Arcs for Mill Lighting.

Textile manufacturers throughout the country for many years have been carrying on experiments in their endeavor to secure an artificial light which would enable their operatives to work with the same facility as in actual daylight, and to produce material in the dark winter days not less perfect than that made in the full light of summer. Gas has long been discarded by the progressive manufacturer as an inadequate and unsatisfactory illuminant, and even the introduction of the Welsbach has had little or no effect in bringing gas back into favor. The necessity of a light which will not falsify colors to the eye and not injuriously affect the latter precludes the use of even the most recent types of improved gas burners.

The series arc lamp of the type commonly used to illuminate the city streets has been, and is even now, in use in many mills. This lamp, with a clear globe, as generally used, has been found too glaring and penetrating, and, while giving a large quantity of light, has proved inconvenient and unsuitable on account of the uneven diffusion of the light, the creation of heavy shadows and the necessity of changing the carbons daily. The inverted arc lamp with the inverted umbrella-shaped reflector has also been tried, and, while the results have been fair, the combination of the large reflector and the lamp is cumbersome and objectionable in appearance, while the necessity of keeping walls and ceilings constantly white is expensive.

The advent of the enclosed arc lamp has, for the first time, given the textile manufacturer a means of illumination which overcomes almost all the different objections and is peculiarly adapted for all classes of mill work. Arc lamps of this type were first developed for direct current and have come largely into use. They have recently been perfected by the General Electric company for use on alternating-current circuits also, and may, therefore, be used either in mills already furnished with their own

direct-current or alternating-current dynamos or taking electricity from systems used to light the city streets.

Enclosed arc lamps have already proved satisfactory illuminants in mill rooms, where spooling skeining, sorting and other delicate work is carried on, as well as in the stock-rooms, dye-houses, etc. The quality and intensity of the light for different requirements and classes of work being susceptible

FIG. 6. INDUCTION MOTORS IN THE DEERING WORKS.—ELECTRIC DRIVE IN SPINNING ROOM. TWINE FACTORY.

of regulation and variation by the use of different translucent globes, an almost ideal light is obtainable, as nearly like that of day as is possible with artificial light. The light from the arc, instead of being concentrated and glaring, is perfectly diffused, eliminating all heavy shadows and allowing of results which could not be obtained by any other artificial means of illumination.

The advantages which the enclosed arc lamp offers will readily be appreciated by the mill owners and mill operators. The carbons burn for a long time; a small number only is required, and the labor of trimming is very small. It is not necessary, therefore, to have a special man occupied solely in trimming arc lamps during the day.

The direct-current enclosed arc lamp burns for about 150 hours with one trimming, that for alternating current about 100 hours. In certain mills, where these lamps have been installed the light is seldom used in summer, and in winter only a few hours daily; under these conditions recarbonizing is necessary only about twice a year, while the cost of carbons is about five cents. Of course, in other mills, where artificial light is necessary for longer periods during dark days or into the night, recarbonizing is necessarily more frequent, but compared with open arc lamps the cost of attendance is very small, while that for carbons shows a marked economy. With open arc lamps a large amount of carbon dust collects in the globe. When the globe is cleaned or dusted out by the trimmer the dust usually settles over everything that may be in the vicinity. With the enclosed arc lamp there is little or no dust, the combustion being almost perfect and any that may be is collected in the small receptacle and held, as it were, in a bottle, to be emptied where it cannot settle on any material or into machinery.

BOOK TABLE.

A very handsome volume is that on "Modern Switchboards" issued in gilt-stamped cloth boards by the Cutter Electrical and Manufacturing company of Philadelphia. It is printed on fine, heavy paper in large type, with wide margins, on pages 9 by 11 inches. The illustrations are beautiful, and several colored plates are very striking. Mr. Albert B. Herrick is the compiler of the work, and acknowledgments are made to Mr Luther Stieringer and Mr. W. H. Tapley. The book treats of general switchboard construction and all kinds of switchboard appliances and protective devices. The types of standard and special switchboards, such as railway, alternating, low tension and the like, are considered in several chapters. Especial attention is paid to the Cutter D. E. circuit breaker, and there are 60 pages of instructions and data included the object of concern interested in switchboard work. The book is one that will be preserved in the engineers' library.

Street-railway Litigation.

An important legal question has been raised in the proceedings instituted by Montgomery Ward & Co. of Chicago against the Chicago City Railway company to restrain the latter from erecting poles and wires in Michigan avenue between Madison and Randolph streets.

It will be recalled that when the City Council passed the order providing for the elevation of steam-railroad tracks at Sixteenth street, the mayor was authorized to grant the Chicago City Railway company permission to establish trolley lines temporarily on State street and Wabash avenue north of Twenty-second street, with the necessary loops, to enable the company to bring Clark street trolley cars into the heart of the business district. The cable cars to haul them. It is admitted that such an arrangement would be impracticable if all the trolley cars now operating on Clark street should be carried over to the Wabash avenue loop.

The street-railway company has therefore endeavored to have set aside the injunction granted in the Superior Court of Cook County, and the case is now in the Appellate Court of Illinois, First District. Following is an abstract from the brief filed by the appellant:

"Complainants allege they are the owners of certain lots abutting upon Michigan avenue, north of Madison street, in the northwest fractional quarter of section 10, known as Fort Dearborn Addition to the city of Chicago; that these lots 'front east upon Michigan avenue and Lake Park;' that the land 'known as Michigan avenue and Lake Park,'

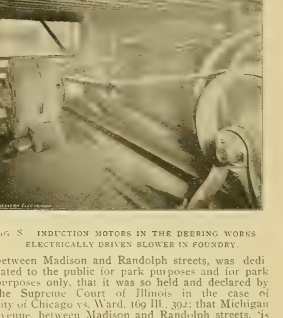

FIG. 8. INDUCTION MOTORS IN THE DEERING WORKS ELECTRICALLY DRIVEN BLOWER IN FOUNDRY.

between Madison and Randolph streets, was dedicated to the public for park purposes and for park purposes only, that it was so held and declared by the Supreme Court of Illinois in the case of city of Chicago vs. Ward, 169 Ill. 392; that Michigan avenue, between Madison and Randolph streets, 'is a part and parcel of said Lake Park, which Lake Park between the east line of said lots and Lake Michigan was dedicated to the use of the public by the government of the United States, not to be occupied with buildings of any description;' that the Supreme Court also held in the Ward case that no encroachments should be made upon said land by any railroad company; that the Chicago City Railway company now operates a street railway upon Michigan avenue, between Madison and Randolph streets, by means of an underground cable,

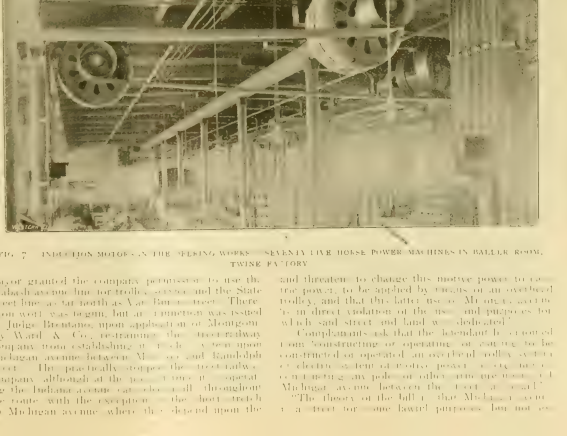

FIG. 7. INDUCTION MOTORS IN THE TWINING WORKS.—SEVENTY-FIVE HORSE POWER MACHINES IN BALLER ROOM, TWINE FACTORY.

[illegible] granted the company permission to use the Wabash avenue line for trolley cars, and the State street line as far south as Van Buren street. There upon work was begun, but an injunction was issued by Judge Brentano, upon application of Montgomery Ward & Co., restraining the street-railway company from establishing a track upon Michigan avenue between Madison and Randolph street. The practically compose the [illegible] complaint, although of the [illegible] upon the ground that the [illegible] ing the Indiana avenue cars [illegible] all throughout the route with the exception of the short stretch on Michigan avenue where they desired upon the and threatened to change this motive power to electric power, to be applied by means of an overhead trolley, and that the latter use of the [illegible] is in direct violation of the uses and purposes for which said street and land were dedicated.

Complainants ask that the defendant be enjoined from 'constructing or operating or causing to be constructed or operated an overhead trolley system of electric railway or electric power system for propelling any passenger or other cars upon said Michigan avenue between the [illegible] a street for [illegible] purposes [illegible]

all lawful purposes; that it is a street in so far that the defendant may operate thereon a street railway by cable power but not by electric power; that while it may be used in fact as a street, that in law it is not a street, but is in some undefined way a park or a portion of a park, and that because the courts have enjoined the Illinois Central Railroad company from making any encroachment west of its west line of right-of-way that therefore these cases, or some language by the courts, operate as a limitation upon the full exercise of the power vested in the municipal corporation of Chicago, to manage, control and use Michigan avenue for all the lawful purposes of a street or highway.

"On behalf of the appellant it is insisted that the court below erred in entering the order for an injunction, because the bill upon its face discloses the fact that Michigan avenue is a public street and is therefore subject to the absolute control of the municipal authorities, and, further, that the purpose for which defendant intended to enter upon the street was a lawful purpose, and hence the complainants have no standing in a court of equity."

In the argument supporting the right of the city government to exercise police powers over Michigan avenue, it is contended that the abutting property owners, by their acts, have recognized the original dedication of Michigan avenue as a street, and that they are now estopped from a denial of the right of the public to enjoy what was thus dedicated. It is shown by the records that "shortly after the property owners, under authority of the City Council, established the east line of the street, and after it was in use by the public from Twelfth street north to the government reserve line, north of South Water street, it was insisted by these property owners that, by the plat of 1829, Michigan avenue was dedicated as a street throughout the entire length of Fort Dearborn addition, and they petitioned the City Council to open such street from the reserve line north to the river."

Attention is called to the fact that the property owners aided in reducing the width of Michigan avenue from 120 feet to 90 feet, and this is cited as clear recognition by them of the street, and it is contended that no reason can be assigned for this action other than that they considered the street as independent of the park. Their solicitude was with reference to the open space beyond the street. It was not the street which enhanced the value of their lots, but the open space beyond. The larger space across the street, the greater area there, was the advantage the lot owners were seeking, because it was this space they understood should remain free from buildings.

The argument in behalf of the street-railway company is summarized as follows: "The bill in this case does not disclose any violation of the trust declared by the original dedication of the public ground in Fort Dearborn addition, nor that any special trust in favor of the lot owners was created by that dedication. It does not negative the legal effect of the acts and conduct of the property owners as set forth in the several cases cited. There is no allegation that Michigan avenue is not a public street, and that it has been so used by the public with the consent of the property owners, and acquiescence of the municipality and state. It is not denied that the appellant company is now in lawful occupation of the street, or that the use of the street by a street-railway company is lawful. No facts are stated from which it appears that the appellant is about to enter upon the street without lawful permission from the municipal authorities or that the purpose of such entry is unlawful. No special injury or damage is shown, and no other equitable ground of relief is set up.

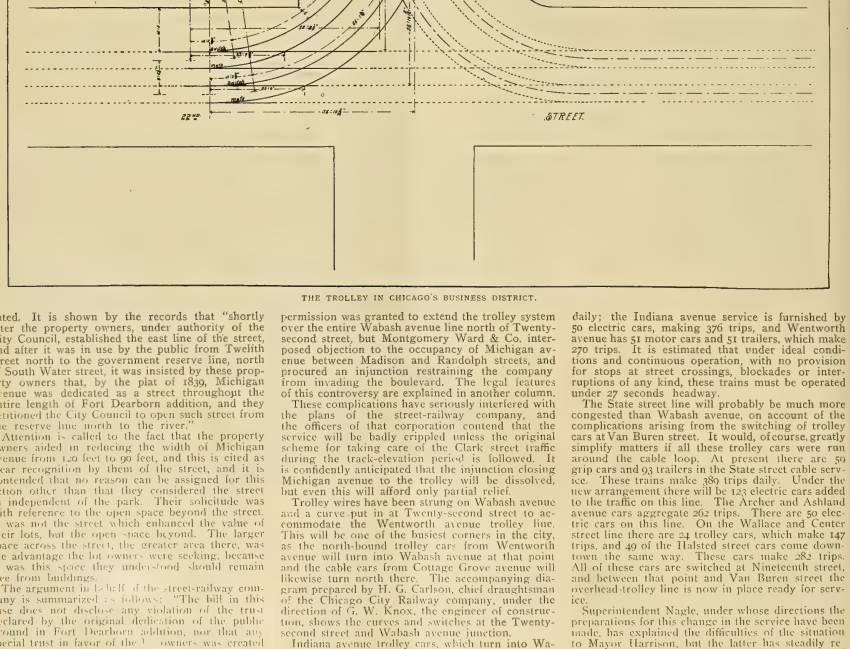
"It is admitted that the appellant may operate a street railway by cable power on this street, but it is denied that it can operate such railway by electric power."

The Trolley in Chicago's Business District.

Everything is in readiness for the operation of electric cars on the State street and Wabash avenue cable lines of the Chicago City Railway company north of Twenty-second street. The mayor has granted permission to place wires and poles in State street, between Twenty-second street and Van Buren, but he has refused to let the trolley lines extend farther north on State street. However, they are hauled or pushed by the cable cars from Madison street north two blocks, where they turn west into Randolph street and secure connection with the trolley for the return trip.

Should the mayor adhere to his policy regarding State street the company will be obliged to turn its trolley cars into Van Buren street and use that street for a switching terminal, as State street is too important a thoroughfare to be blocked in this manner. This plan is very satisfactory to the big department stores that occupy the west side of State street at that point, as it will bring to their doors all the passengers from the southwestern section of the city that now patronize the Clark street line. It will undoubtedly be a considerable surprise to many to learn that the trolley cars that will be brought to this point carry 85,000 paying passengers per day, more than twice the number carried on the State street cable line.

One of the most difficult tasks in connection with the change of route of the trolley cars is the arrangement of a time card. All the cars of the South Side system are run on schedule time, and every detail is carefully considered before any change is attempted. A great many factors must be considered in preparing such a schedule, otherwise all would be confusion. Provision must be made for operating 388 cars on the Wabash avenue loop. There are 86 grip cars and 150 trailers on the Cottage Grove avenue line, making 502 trips daily; the Indiana avenue service is furnished by 50 electric cars, making 376 trips, and Wentworth avenue has 51 motor cars and 51 trailers, which make 270 trips. It is estimated that under ideal conditions and continuous operation, with no provision for stops at street crossings, blockades or interruptions of any kind, these trains must be operated under 27 seconds headway.



THE TROLLEY IN CHICAGO'S BUSINESS DISTRICT.

The State street line will probably be much more congested than Wabash avenue, on account of the complications arising from the switching of trolley cars at Van Buren street. It would, of course, greatly simplify matters if all these trolley cars were run around the cable loop. At present there are 59 grip cars and 93 trailers in the State street cable service. These trains make 389 trips daily. Under the new arrangement there will be 123 electric cars added to the traffic on this line. The Archer and Ashland avenue cars aggregate 262 trips. There are 50 electric cars on this line. On the Wallace and Center street line there are 24 trolley cars, which make 147 trips, and 49 of the Halsted street cars come downtown the same way. These cars make 282 trips. All of these cars are switched at Nineteenth street, and between that point and Van Buren street the overhead-trolley line is now in place ready for service.

Superintendent Nagle, under whose directions the preparations for this change in the service have been made, has explained the difficulties of the situation to Mayor Harrison, but the latter has steadily refused to give his consent to the establishment of a trolley loop on the State street cable line.

permission was granted to extend the trolley system over the entire Wabash avenue line north of Twenty-second street, but Montgomery Ward & Co. interposed objection to the occupancy of Michigan avenue between Madison and Randolph streets, and procured an injunction restraining the company from invading the boulevard. The legal features of this controversy are explained in another column.

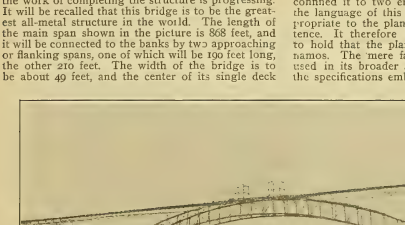
These complications have seriously interfered with the plans of the street-railway company, and the officers of that corporation contend that the service will be badly crippled unless the original scheme for taking care of the Clark street traffic during the track-elevation period is followed. It is confidently anticipated that the injunction closing Michigan avenue to the trolley will be dissolved, but even this will afford only partial relief.

Trolley wires have been strung on Wabash avenue and a curve put in at Twenty-second street to accommodate the Wentworth avenue trolley line. This will be one of the busiest corners in the city, as the north-bound trolley cars from Wentworth avenue will turn into Wabash avenue at that point and the cable cars from Cottage Grove avenue will likewise turn north there. The accompanying diagram prepared by H. G. Carlson, chief draughtsman of the Chicago City Railway company, under the direction of G. W. Knox, the engineer of construction, shows the curves and switches at the Twenty-second street and Wabash avenue junction.

Indiana avenue trolley cars, which turn into Wabash avenue at Eighteenth street, are now operated electrically, excepting on Michigan avenue, where

Trolley Road Crossing Niagara Gorge.

The main span of the new steel arch bridge across the gorge at Niagara Falls has been sprung, and the work of completing the structure is progressing. It will be recalled that this bridge is to be the greatest all-metal structure in the world. The length of the main span shown in the picture is 868 feet, and it will be connected to the banks by two approaching or flanking spans, one of which will be 190 feet long, the other 210 feet. The width of the bridge is to be about 49 feet, and the center of its single deck



TROLLEY ROAD CROSSING NIAGARA GORGE.

will be taken up by double tracks for an electric-road service across the river. There will also be carriageways and footpaths.

The work of erecting this great arch has been most interesting. The top chords of the shore spans were sent out along the suspension bridge, which the arch is to supplant; the end posts were erected, and then piece by piece the wonderful arch grew out from both sides at the same time until the two sections met and were joined in the center of the river high over midstream. As every two sections of the arch were placed strong anchors were sent down to them from the top chord to sustain their weight, the picture showing these anchor cables very clearly. The arch is expected to be completed during the summer, and it will rank high as an engineering feat.

Rubber Companies Consolidate.

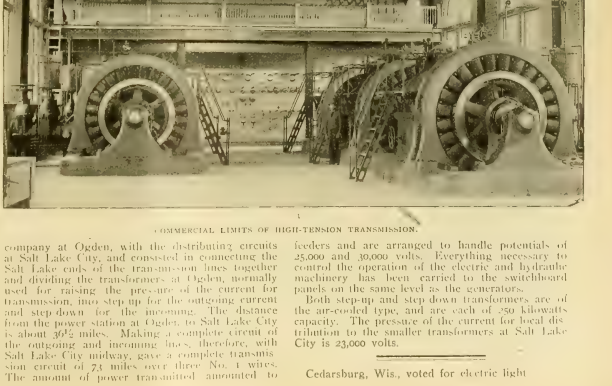
By the recent incorporation at Albany of the American Hard Rubber company of New York city, with a capital of $2,500,000, the Butler Hard Rubber and the India Rubber companies of New York and the Goodrich Hard Rubber company of Ohio go out of existence. The headquarters of the new company will be in New York, and the directors are Fritz Achelis, Richard Butler, Charles A. Hoyt, Edwin W. Belcher, Jr., Albert T. Morse, William W. Welting and Frederic G. Dow of New York and George T. Perkins and Henry C. Carson of Akron, O. Its only rival will be the Goodyear Vulcanite company of Pennsylvania. The new company is said not to be a trust, as the companies which cease to exist as corporations sell out and lose their identity in absolute consolidation. The fusion came of the conviction that it would be admirable business policy for the majority of the hard-rubber interests to work to one end in a corporate fusion. The American company will confine its manufacture wholly to hard rubber, and its products will be principally combs and appliances for electricity.

Very Limited Definition of "Plant" Upheld.

The specifications in an installation contract were divided into various subdivisions, such as "plant," "engines," "dynamos," etc. One of these subdivisions was: "Plant: The plant shall consist of two engines and two dynamos," with certain other provisions. This gave rise to the question as to what the term "plant" so used covered. It was contended, on the one hand, that this contract meant a plant as defined by Houston's Electrical Dictionary: "Plant—a word sometimes used for installation, or for the apparatus to carry on any manufacturing operation. An electric plant includes the steam engines or other motors, the generating dynamo or dynamos, the lamps and other electro-receptive devices, and the circuit connected therewith." But the Supreme Court of Michigan says, March 15, 1898 (Fisher Electric company against Bath Iron Works), that the parties had, in the subdivision of the contract, seen fit to define the plant to which the provisions of the subdivision applied, and had confined it to two engines and two dynamos. All the language of this subdivision was peculiarly appropriate to the plant as described in the first sentence. It therefore maintains that it was correct to hold that the plant meant the engines and dynamos. The mere fact that the term "plant" was used in its broader sense in other subdivisions of the specifications embraced in the contract, the Supreme Court declares, did not affect the construction of the term as restricted by the subdivision in question. This decision furnishes a hint of the care that should be exercised in drawing contracts.

Commercial Limits of High-tension Transmission.

An interesting experiment in high-voltage, long-distance, electric-power transmission was recently made at Ogden, Utah, in order to ascertain the limits within which high-voltage currents might be used commercially. The experiment was made by F. O. Blackwell of the General Electric company over the lines which connected the power station of what was, until recently, the Pioneer Electric company at Ogden, with the distributing circuits at Salt Lake City, and consisted in connecting the Salt Lake ends of the transmission lines together and dividing the transformers at Ogden, normally used for raising the pressure of the current for transmission, into step up for the outgoing current and step down for the incoming. The distance from the power station at Ogden to Salt Lake City is about 36½ miles. Making a complete circuit of the outgoing and incoming lines, therefore, with Salt Lake City midway, gave a complete transmission circuit of 73 miles over three No. 1 wires. The amount of power transmitted amounted to 1,000 horse power, and the voltage at which the transmission was effected reached at times as high as 30,000 volts. The current on the return was delivered to resistance vats at the power house, consisting of three wooden tanks.



COMMERCIAL LIMITS OF HIGH-TENSION TRANSMISSION.

By careful and repeated measurement with wattmeters at both ends Mr. Blackwell ascertained that this power was transmitted with the loss of only nine per cent., including four per cent. loss in the two sets of transformers. The drop in pressure due to inductance was practically nil, the capacity of the line being sufficient to compensate for reactance loss.

Continuing the experiment, part of the Salt Lake City station load was run from Ogden, with current at 24,000 volts. This was supplied to about 500 horse power in synchronous motors and lights for two days, under most severe climatic conditions—rain, fog and snow alternating. In addition a severe thunderstorm prevailed all through the night, the lightning arresters discharging repeatedly. Notwithstanding the severity of the conditions under which the test was made, the motors operated without failure and the lights burned without flickering, even during the times of lightning discharges. Not the slightest difficulty of any kind developed while this experiment lasted.

By the recent accomplishment of a scheme of consolidation all the electrical plants in Salt Lake City, as well as the transmission plants, supplying current from it to the outside, have been merged into the Union Light and Power company. The companies thus consolidated were the Pioneer Electric Power company, the Salt Lake and Ogden Gas and Electric company, the Big Cottonwood Power company, the Little Cottonwood Power company, the Citizens' Electric Light company and certain smaller interests.

The plant of the Pioneer Electric Power company is one of the most important installations in the West and the transmission one of the longest. The power house is located a short distance from the mouth of the Ogden Canon. The power is derived from the Ogden River, the water being brought to the power house through a wooden-stave pipe and riveted steel-pipe line, about 32,000 feet long. The electric plant consists of five General Electric three-phase alternators—24-pole machines running at 300 revolutions, and delivering 750 kilowatts each at 2,300 volts and 60 cycles. The complete plant is designed for 10 units, or a total output of 10,000 horse power. The exciters are General Electric six-pole, 500-volt kilowatt dynamos, each of ample capacity to excite 10 generators. Each alternator is directly connected to a Knight water-wheel of 1,200 horse power capacity, and each exciter to one of 135 horse power capacity.

The current is fed into the transmission lines from the step-up transformers at 16,100 volts, and delivered to the step-down transformers at 13,800 volts. They are ordinarily connected in delta, but can also be connected in "Y" to raise the potential to 25,000 volts whenever it is desired to run at the higher potential in order to increase the capacity of the line or the distance over which the power is to be carried. The switchboard panels on the gallery at the end of the power house are for the outgoing feeders and are arranged to handle potentials of 25,000 and 30,000 volts. Everything necessary to control the operation of the electric and hydraulic machinery has been carried to the switchboard panels on the same level as the generators.

Both step-up and step down transformers are of the air-cooled type, and are each of 250 kilowatts capacity. The pressure of the current for local distribution to the smaller transformers at Salt Lake City is 23,000 volts.

Cedarsburg, Wis., voted for electric light

Western Electrician

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO.

TELEPHONE, MAIN 1746.

EASTERN OFFICE: 108 TIMES BUILDING, NEW YORK.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN — **the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

HIGH WATER MARK

CIRCULATION, 20,000.

Four Years' Record of Electric Light Convention Advertising.

Issue	Number of Advertising Pages.	Whole Number of Pages.	Square Inches of Paid Advertising-Matter.

The solution of the Hawaiian problem may yet be found in the present Spanish complications. Although it seems to be understood that the islands have not been annexed by the United States, it is not at all certain that such a plan will not be adopted. At any time it may be determined that that important group is necessary to the safety of this country, and if the United States once takes possession the establishment of cable communication between Honolulu and Washington must necessarily follow.

The foreign business of American electrical manufacturers has made remarkable advancement of late and is attracting the attention of European countries. The English Consular Bureau has made a report to the effect that the principal imports of machinery into British Guiana are from the United States, and that they are mostly in connection with the installation of electric-light plants. Special legislation is proposed by the French Chamber of Deputies for the increase of the tariff duties that have been in force since 1892. Several measures are now under consideration which, if enacted, might seriously affect trade between this country and France. For instance, the maximum tariff on electrical accumulators would be increased from $3.28 to $4.05, and the minimum duty from $2.50 to $3.18 per 100 kilogrammes. It is also proposed to impose a heavier tax on motor cars imported from this country, as American types are the only ones which offer serious competition to the French product.

Representatives of the Northwestern Electrical association are now in the East completing arrangements for the attendance of several prominent electrical men at the summer convention which is to be held in June, immediately after the annual meeting of the National Electric Light association at Chicago. The organization has extended invitations to Edison, Tesla, Thomson, Brush, Stanley and Wood, as representatives of the inventors who have contributed to the success of the electric-lighting and power industry. The city officials of Duluth and West Superior have also issued invitations to the same gentlemen, and it is believed by the committee that they will accept the hospitality of the association and the cities mentioned. During the convention many practical topics will be discussed by men of ability and recognized standing in the profession, and the gathering is expected to be one of the most profitable as well as the most entertaining that has yet been held by this progressive organization.

When the trolley line between Buffalo and Niagara Falls was established an arrangement was made by which the cars of this system were permitted to enter Buffalo on the tracks of the local street-railway company. The plan did not affect the regular service in any way, but proved a great convenience to the patrons of the Niagara Falls-Buffalo line, who otherwise would have been compelled to change cars at the city limits. Many patrons of the Buffalo system insisted upon riding upon the cars of the Niagara Falls-Buffalo line, and frequently presented transfers, which of course were not accepted. The annoyance to the street-railway companies as well as to the dissatisfied patrons led to consideration of the subject by the city law department. The corporation counsel has prepared an opinion in which he sustains the position of the street-railway companies. He says as long as a sufficient number of cars are operated by the Buffalo company to accommodate the patrons of the local system there is no ground for complaint and that corporations of this character have the right to make reasonable rules and regulations. He believes the arrangement complained of is a reasonable rule from a legal standpoint, and accordingly determines that the company is acting within its powers in enforcing its regulations.

The success which has attended the efforts of American engineers in Great Britain has attracted even greater attention in Europe than in this country and has encouraged many to seek assistance through similar channels in developing electrical industries on the Continent where the natives have neglected the natural advantages, particularly in power transmission. There seems to be a lively interest in the subject just now in Italy, where many villages have made use of water power for the operation of electric-light plants. But this has not been done in many instances, and it is pointed out that good opportunities are presented. For instance, the town of Amalfia, which is a favorite resort of travelers in the winter season, is furnished with excellent hotels, and has a torrent of water running right through it which works numerous paper mills and several macaroni factories. According to local authorities, to install an electric-light system there would be neither costly nor difficult, and it is believed that it would pay handsomely on the investment, as the large hotels alone would guarantee remunerative returns. In Naples, which is supplied with a continuous current at 110 volts, German lamps are used, of very inferior quality both in the color of the globes, the finish and light-dispensing power. It has been suggested that American manufacturers, by encouraging American engineers, might open up an excellent market for electrical supplies of all kinds as well as heavy machinery throughout Europe. At the present time American methods are in favor, American engineers are in demand, and it is but natural to suppose that American goods would find ready sale if properly pushed in these markets.

Mention has already been made of the decision by the United States Circuit Court of Appeals in the case of the city of Richmond against the Southern Bell Telephone and Telegraph company. The opinion construes the words "telegraph companies," as used in the act of Congress of 1866, to include telephone companies. It contends that the telegraph and telephone both communicate messages by means of electricity over wires, for longer or shorter distances. The telegraph communicates these messages by sound of instruments, the telephone by the human voice usually. Both depend upon electricity for their action. Each is but a form of use—the product and result of the same principle. The different names are used only to distinguish the method of communication. Therefore, the court holds, a telephone company is within the protection and enjoys the privileges of the act of Congress of 1866, authorizing telegraph companies to construct, maintain and operate their lines over and along post roads of the United States, but so as not to interfere with ordinary travel. At the same time, it holds that these privileges must be enjoyed, subject to the lawful exercise of the police power, and, while the municipality can establish such lawful provisions as may regulate the use, the court holds that it must, however, refrain from making regulations which will make the use burdensome and intolerable, and so practically impossible.

The establishment of governmental censorship over private telegrams and press matter is a condition unknown heretofore to the present generation of Americans, but it is safe to say that the measure will be accepted in good part by the people as long as it is considered necessary for the vigorous prosecution of the war against Spain. The United States government has seized the cable office at Key West and has cut the cable to Havana. Of course all government business has precedence in transmission, and press and commercial matter is subjected to a strict censorship. All dispatches are supposed to be sent in the order that they are filed, but dispatches that contain matter that is objected to are laid aside, and corrections that are demanded by the censor are made. They are then refiled as new messages. The amount of business offered at the cable office is so great that the censor has his hands full day and night, and great delay under the present arrangement is unavoidable.

Spain has, of course, long since exercised supervision over all telegrams forwarded and received within her domains, and, as related elsewhere, this censorship enabled her to cut off diplomatic relations with the United States before the ultimatum was delivered by General Woodford at Madrid.

The cutting of the cable at Havana is accepted by many as lending color to the statement that the United States would destroy the Spanish cable and thus cut off Cuba from communication with the rest of the world. It is to be hoped that this course will not be found necessary. The American doctrine of preserving the neutrality of the cable systems of the world is gaining ground rapidly, and if this country now practices cable-cutting it will very materially retard the universal acceptance of such a plan. Another consideration which should not be lost sight of entirely is the fact that the so-called Spanish cable is owned largely by English capitalists and that there is no doubt but that complications will arise in case their interests are injured.

WAR NEWS.

General Telegraphic Communication Restricted.—Now that hostilities have been begun, the newspapers will find it difficult to telegraph prompt and reliable news of the doings of the United States fleet in Cuban waters, as the government will see to it that no information prejudicial to its plan of campaign is transmitted through the regular channels. Official notice was given on April 24th that a censorship had been established by the government of the United State at Key West and that code or cipher messages to and from Cuba were forbidden to the public. As shown on the map recently published in the Western Electrician, Key West is a very important point on the cable line from Florida to Cuba, as the wires are laid in the Gulf of Mexico, from Punta Rassa to Key West, and from Key West across the Florida Strait to Havana. The cable office at Key West is now under supervision of the government. Capt. R. E. Thompson, United States Army, signal-service corps, is in charge. The instructions issued to press correspondents prohibit forecasts of the movements of troops and of the army and forbid improper criticism of officers. Advices of engagements between opposing fleets must go first to the department at Washington. Press matter may follow.

At Washington, largely through the efforts of Assistant Secretary Meiklejohn, the building sheltering the War and Navy Departments is now provided with exceptional telegraphic facilities. The office is provided with a large switchboard, with 25 independent wire connections, being a miniature of the large switchboard in the main office of the Western Union Telegraph company. There is also a complete system of loops whereby the secretary of war and his assistants are enabled to communicate almost directly with all telegraphic places in the world. This is in addition to the direct communication afforded by the government wires connecting the War Department with the White House, the capitol, all the executive departments and the army posts at Fort Myer and Washington Barracks. It is asserted that a special private "war chamber" has been fitted up at the executive mansion for the president's use. This apartment is said to be provided with maps, charts, books and papers, telegraphic and telephonic connections and all paraphernalia that will assist in securing confidential information or aid in consultation. An extra force of trusted operators has been secured by the government to handle the war dispatches. Precautionary measures are being made to secure secrecy. All telegraph operators have been warned that it will be considered treason to make public any of the messages received.

Much has been published in relation to the cutting of telegraphic cables in Cuban waters. It appears to be pretty certain that United States naval officers have cut the direct American cable connecting Key West and Havana, but as to the other West Indian cables the newspaper reports are conflicting. As to the Key West cable, it is stated positively that the cut was made about 10 miles out of Havana, and that the southern end of the cable is now moored to a buoy. The Mangrove was recently converted into an auxiliary cruiser, with a complete cable outfit. This gives the government exclusive use of the cable and cuts off a possible source of communication between Cuba and Spain. It is said that the insurgents are between Havana and the other cable ports. It is said to be intended, as soon as the blockade of the southern ports of Cuba is established, to cut the cables between those points and South America, thus entirely severing telegraphic communication between Cuba and the outside world, except such matter as is sent through the United States censorship.

Orders have been issued by the Navy Department to prevent the newspaper boats from following the fleet, thus doubling the difficulty of obtaining accurate information, as well as greatly delaying it.

The exact intention of the government in relation to the French and British cables in the West Indies is not known, if, indeed, a plan has been formulated. The London Times protests against the intention attributed to the United States to cut a cable belonging to English companies, and expresses the hope that America will not establish so evil a precedent, which might be held by Spain to justify the cutting of any cable landing on American soil. It is not believed, however, that serious complications will grow out of the situation, as the international agreement on the subject of submarine cables only provides for times of peace. It is also pointed out that offenders can only be tried in their own country.

Electricians in the Service.—The Boston correspondent of the Western Electrician writes that many electricians in Massachusetts are volunteering their services to the United States. Representative ?. H. Hoyt of Haverhill has already accepted a position with the government and has been assigned to electrical work in the signal service of the district which extends from Chatham north to the New Hampshire line. This work is under the supervision of Lieut. Sewall, U. S. A. Mr. Hoyt sent in his resignation several weeks ago, to take effect as soon as war was declared, but it was afterward discovered that he could hold his seat in the Legislature although he was in the employment of the United States. City Electrician Edward Hesselton of Haverhill has also tendered his services to the government.

The Navy Department is enlisting qualified men for the ratings of electrician. Applicants must be capable of performing all duties pertaining to the care, preservation and manipulation of a ship's electric-lighting plant and its appurtenances, together with all other electrical appliances; they must also be physically qualified. First enlistment is made in the rating of electrician, second class ($35 per month), with possibility of future advancement to electrician, first class ($40 per month) and chief electrician ($50 per month). In addition to the pay stated, there is a ration allowance of 30 cents per day. Enlistments in this rating are made only at the navy yard, Brooklyn, N. Y.

It is stated that a separate division of the naval reserves is being organized by Frank J. Sprague in New York. It is to consist of about one hundred men, one-half of whom are to be electricians and the remainder telegraph operators and signal-men.

Carl F. R. Hartmann of Newark, N. J., is organizing a signal corps to work with the volunteer forces in war, and has already gathered about a dozen telegraphers, electricians and surveyors. The membership of the corps is to be limited to 40.

Diplomatic Dispatch Tampered With.—The delay of General Woodford in presenting to the government of Spain the cabled ultimatum of President McKinley, which enabled the Spanish cabinet to "save its face" by breaking off diplomatic relations, is explained by the assertion that the message did not reach the American minister at the time it should have done, being withheld by the telegraphic authorities in Madrid and submitted to the Spanish government. It is charged that the dispatch was an open one, in plain English, and that it was received in Madrid at 11 o'clock on Wednesday night, April 20th, and was held by the government until three o'clock Thursday morning. Meantime the Spanish note was prepared, and was delivered to Minister Woodford at seven o'clock in the morning. By means of this duplicity, it is claimed, the Spanish government was able to avert the reception of the ultimatum.

Electrical Work Along the Coast.—The greatest activity in the preparation of the coast defenses for a state of war is still manifest, and of course the installation of electrical apparatus for communication, for the firing of torpedoes or mines, for searchlights or for other purposes, is an important part of the work. New York harbor is now pretty well prepared. General Greely, in charge of the telegraph and telephone communication between seacoast fortifications, has announced that the New York harbor cable to Sandy Hook is completed; also those to Fort Wadsworth and to Fort Schuyler. Work on the signal stations along the south shore of Long Island and on the telegraph and telephone lines to connect the forts and works with New York is progressing toward completion. The signal station at Quogue has been completed, and the one for Southampton is under way. The signal towers are to be manned by the New York naval reserves, and rockets and lights will be used for night signals and block signals for day work. These towers are for the purpose of announcing the approach of hostile vessels toward the coast. A difficulty has been encountered in the waters near New York. Off Fort Wadsworth it has been found that shad fishermen, whose nets have been spread there, have not hesitated to cut the cables of mines and torpedoes already planted. After this discovery the boats from which the engineers were working were armed with the rifles of the men. The Narrows are now patrolled every night, and a strict watch is maintained by day. The first fisherman caught cutting cables will be arrested and the next one may be shot on sight.

A New York paper of Monday says that the powerful searchlights at Sandy Hook were kept going all Saturday night and again Sunday night. The long rays were sent in all directions, and frequently were turned into the Lower Bay and into the Narrows. At times from South Beach every buoy in the channel could be made out, and all craft in the Lower Bay were seen clearly and plainly.

Galveston harbor has been mined. All of the torpedoes have not yet been placed, but enough have been put down to insure the safety of the harbor from hostile vessels. The bar pilots will be given courses to steer clear of the torpedoes, and they will be advised to move vessels through the channel at the slowest possible speed, only going fast enough to give the vessel steerage way. The wires which will be used to fire the mines have been laid and tested. Of the 50 circuits all worked satisfactorily except four.

A coast signal station has been established at Block Island, R. I., opposite Montauk Point. A gentleman of Providence has tendered his summer residence for the station, and the detail consists of a lieutenant and six men from the naval reserve battalion at Newport. The laying of mines and the wiring in the passages to Narragansett Bay have been begun.

The torpedo station at Portland, Me., has recently been equipped with a dynamo, and this is now ready for use. The electric batteries at Portland Head have also been installed, and the mines so far laid are ready for use. Other harbors and the rivers along the Maine coast are to be protected by torpedoes. This work will be done as soon as the government engineers complete the defenses of Portland.

With other cable manufacturers, the Standard Underground Cable company of Pittsburg is very busy on government work. J. W. Marsh, vice-president of the company, says that the cost of these cables will be from $40,000 to $50,000, and even though night and day is being spent in constant work upon them, the contract can scarcely be filled this month, and it will run far into May. The contract calls for single-wire and seven-conductor cables. Most of it is to be used in making connections between the land and the submarine torpedoes and mines that are to be operated by electricity, but there will be some underground cables for the forts.

The work of fortifying the approaches to the harbor at Norfolk, Va., by means of submarine mines is now about complete. The supplying of Fort Monroe with the great 60-inch searchlight which was used at the World's Fair and its equipment with a modern battery of rapid-fire guns for use against torpedo boats and light-draught gunboats have greatly increased the fort's efficiency.

The work of laying cables, anchors and buoys in Hampton Roads and at the mouth of the Chesapeake Bay is rapidly nearing completion, and will in a few days be sufficiently advanced to permit of the submarine mines, now closely guarded in the Fort Monroe arsenal, being attached within 24 hours after the order is issued. The principal keyboard operating this deadly network of mines is located in the "holy of holies" inside Fort Monroe, where no outsider is permitted to go. Another keyboard is also operated from Cape Henry.

Use of the Telephotos.—The War Department has decided to erect sets of the telephotos at the fortifications at Boston, New York, Fort Monroe, Key West and San Francisco, so that news, instructions and general communications can be transmitted by night as well as by day between the army fortifications, which will be in telegraphic communication with Washington, and the fleets or vessels of the navy which may be under the guns of the forts or in adjacent waters. At any moment it may be of the greatest importance to communicate with the vessels of the navy from the shore after nightfall, and with a set of telephotos on a mast or at a fort, instant communication may be had. At the fortifications, where the telephotos are first to be put in, an electric plant, suitable for the working of the signals, is already established. It is also the intention of the government to equip other stations along the coast with these signals, and a plan for a small power plant, suggested by Mr. C. V. Boughton, the inventor of the telephotos, is likely to be adopted. Mr. Boughton advised that a small automatic gasoline engine, connected to an incandescent dynamo of a size sufficient to supply the lights for the telephotos, could be installed at a small cost, and could be run without requiring the services of a skilled engineer or attendant. It is probable that such plants will be installed along the seaboard, where sections of the coast-guard fleet will lie.

A Poor Joke.—This advertisement, which appeared in several of the New York papers, caused more than a little trouble recently:

"Electricians to go to the front at once, under the supervision of an expert; first-class men only as volunteers; construction, incandescent and bell men preferred.—J. W. Sisk, No. 105 Broadway."

From early morning until noon, says the New York Tribune, electricians of all sizes, ages and kinds appeared at No. 105 Broadway, which is the Western Union building, and were referred to the fourth floor of the building. The elevator men carried up and down the largest crowds of the year, and got tired of answering questions. The advertisement was the work of a practical joker. J. W. Sisk is the wire and electric-light man of the building, and someone who knew that he was to be away yesterday caused the advertisement to be inserted.

It would not have been good for the practical joker to have acknowledged in the presence of the applicants the authorship of the joke. Martin Sisk, a brother of the man whose name appears in the advertisement, and who is a lineman, appeared in the crowd and proceeded to make merry, but his jocularity was cut short by the angry and duped applicants, all of whom appeared to be greatly chagrined at having no opportunity of going to the front.

Holland Submarine Boat.—Mr. Holland says that he has had an offer from France for his submarine torpedo boat, but he wants to sell it to his own government. He asks $175,000 for the vessel. Mr. Holland has made the remarkable proposition to go to Key West, join Admiral Sampson's squadron, and with his own crew enter the harbor of Havana by night and throw a dynamite bomb into Morro Castle. Mr. Holland will undertake this if the government will guarantee to purchase the vessel at the conclusion of the performance. The strategy board fully recognized the tremendous moral effect such an assault would have upon the Spaniards, if successful, and was disposed to agree to the terms, but the civilian authorities of the navy have preferred to take the matter under further consideration.

Miscellaneous Notes.—Representative Hull, chairman of the military affairs committee has introduced a bill to increase the efficiency of the

[*Continued on page* [illegible].]

DEVELOPMENT OF THE TELEPHONE FIELD.

Auxiliary Signals as Applied to the Telephone.

By H. P. Clausen.

Ordinarily a telephone station need not be supplied with more than one audible signal receiver; at times, however, it is necessary to meet conditions where an auxiliary signal must be installed. The writer believes that an article descriptive of auxiliary

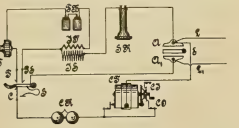

FIG. 1. AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

apparatus might prove of considerable interest to the telephone-exchange superintendent and his assistants. It is to be hoped that the reader who desires to make practical use of some of the suggestions offered is sufficiently familiar with telephone apparatus so that a reference or sketch pertaining thereto may be readily understood, even if it does refer in part to apparatus not described in detail, as such descriptions would not be within the

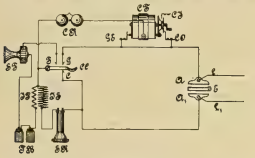

FIG. 2. AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

limited scope of an article which in reality is intended to deal with extension bells.

The well-known magneto ringer that sounds a continuous alarm when supplied with an alternating current of the proper character will be considered as forming a part of all telephone instruments that may be referred to. The driving gear of the magneto generator, it will be assumed, is arranged with

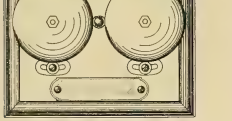

FIG 3 AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE

the necessary provisions for automatically shunting its armature winding out of circuit, and also for connecting its winding to another circuit whenever the machine is operated with the intention of transmitting a call.

Two methods are shown for interconnecting the parts of a telephone station. Fig. 1 represents the most common type. It is employed almost exclu-

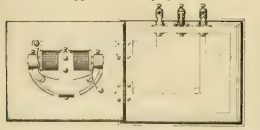

FIG. 4. AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

sively by builders of telephone instruments for use by the independent companies, and for the sake of distinction we will name it the "cut-out method," which term in fact is quite appropriate, for when the telephone hook C C is allowed to move upward, its contact with C is broken, thus cutting out the magneto bell C R and the magneto generator C T. A downward movement cuts out the transmitting and receiving apparatus. In Fig. 4, however, a method is shown where the desired combination of circuits is produced by a "shunting method." Most any make of telephone may be equipped with this method of wiring, which is shown quite clearly in the cut. One fact, though self-evident, should be mentioned in connection with a reference to the "shunting method," namely, that if either by design or accident both the C and G springs be broken, or entirely removed from contact with the hook switch C C, the calling or talking circuit is not destroyed, for the calling circuit finds an easy path through the telephone receiver and the secondary winding of the induction coil, whereas the talking circuit is continuous through the magneto ringer and over the shunt wire of the generator. An amusing case came to the writer's notice where the engineer of a telephone company returned to the maker a telephone instrument wired on the shunting plan, and explained that the instrument had been rejected because "there certainly must be something radically wrong with an instrument that would ring or talk with but one hook spring in place." When it is considered that the engineer experienced at the time

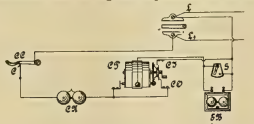

FIG. 7 AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

a great deal of trouble from poor hook contacts the remark can better be appreciated.

Fig. 3 shows an outside and Fig. 4 an inside view of the magneto-extension bell. The type of instrument is well known, and requires no further description. In Fig. 5 an extension bell is shown connected in series with the line wire L'. The switch S is connected across the extension-bell terminals, and when the switch lever is moved to the right it short-circuits the bell terminals. The extension bell employed should be wound to a very low resistance, and even then it offers an unnecessary resistance to

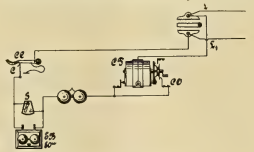

FIG. 6. AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

the passage of the telephonic currents. However, with the same type of bell and switch placed in the telephone circuit as indicated by Fig. 6, it is cut out of circuit whenever the hook switch CC is allowed to produce a talking circuit. As a general rule, the extension bell is placed in a different room than that containing the telephone instrument; therefore, when anyone desires to call the central office he must, before calling, cut out the extension bell, for if this were not done it would cause the sounding of a false signal in the room where the extension bell may be located. Furthermore, even if the switch

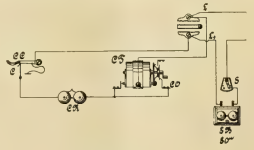

FIG. 5. AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

is cut off when calling the central office, the user when he had finished might neglect to restore the switch to a position allowing the extension bell again to form a part of the calling circuit. For the purpose of avoiding this at times very serious objection to the use of an extension bell, the method shown in Fig. 7 may be employed with good results. Normally the extension bell forms a part of the calling circuit with a branch wire connecting to the normally open "cut-in" spring C I. The switch S may be employed, but it is not required to be operated, as explained in Figs. 5 and 6, for when the magneto generator is operated with the purpose of originating a call, the shunting arrangement with which the crank-shaft is provided makes contact with the "cut-in" spring C I, thus automatically short-circuiting the extension bell. The method is thoroughly practical, and can be applied to most instruments employing a generator shunt operated by a direct movement in some part of the armature driving gear.

Quite often ordinary exchange telephones are placed two or more in series, that is, looped in on one circuit, but this plan is not to be recommended. Suppose we have a circuit containing five telephones, and that it is necessary to place an extension bell at each station. As it is, the five-bell coils already in the circuit prove an objectionable barrier

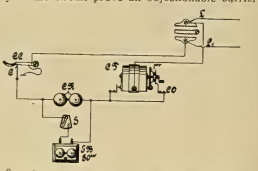

FIG. 8. AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

to the telephonic currents, and the addition of five extension bells might destroy all attempts at giving a satisfactory service. Such would indeed be the fact were it not for the plan suggested by Fig. 8, that is, of connecting the extension bells in multiple with the bell coils of the telephone, the switch S cutting the extension bell in and out of circuit as desired. When all extension bells are in circuit, however, the talking service has been improved merely because

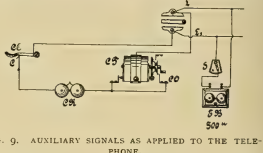

FIG. 9. AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

the resistance offered by every telephone instrument has been halved by the addition of another bell connected in parallel with itself; in other words, if each bell measures 80 ohms, and with 50 ohms line resistance, a series of five bells would give us 450 ohms. Now if we add the extension bells, each 80 ohms, we have reduced the resistance to 250 ohms, whereas if the bells had all been connected in series a resistance of 850 ohms would have been produced, which is quite enough to bar ordinary voice currents.

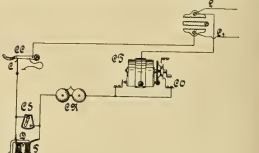

FIG. 10. AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

Specially high-wound extension bells may be employed quite freely, and connected to any point of the telephone line. One rule, and it is a good one, is never to cut a wire or open a circuit when connecting a high-wound extension bell to a telephone line. Fig. 9 indicates the common method of connecting the high-wound bell. The switch S must allow an opening and closing of the bell circuit to one of the line wires. The term high-wound, if

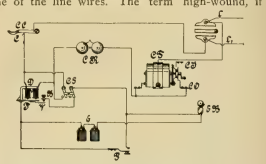

FIG. 11. AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

used when speaking of magneto ringers, may imply any resistance of more than 500 ohms, governed, however, by the conditions to be met.

In the preceding section reference has been made wholly to the auxiliary signals whose operation depended on the current generated at some distant station. Though it undoubtedly is the most economical plant, it is not always sufficiently flexible for allowing special requirements to be met. The ar-

rangement shown by Fig. 10 is in reality a simple annunciator drop, such as might be found in most any central-office switchboard, and an incoming call is registered by the falling of a disk. Fig. 11 illustrates the same arrangement with the addition of a local battery and an electric bell, whose continuity is normally broken at the contact points N and B. An incoming calling current, passing through the winding of the magnet D, causes the latter to attract the armature T, which allows the shutter S to fall and force the spring N into contact with the point B, thereby completing the local circuit and causing the electric bell A to sound a continuous alarm, until either the shutter S is restored to its normal position, or the switch C S is thrown to the extreme left side. The push-button P, connected as indicated, is quite a convenience when it is desired to call one of several persons within hearing distance of the bell A, a prearranged code of signals being employed to call the one whose presence may be required at the telephone. However, for the purpose of meeting the demand for an instrument that will give a code signal as it is sent through the telephone by the central-office operator, an instrument has been arranged as shown by Fig. 12.

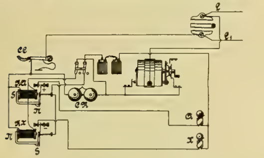

Fig. 13.

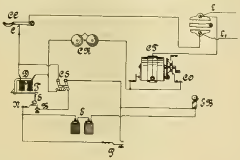

Fig. 12.

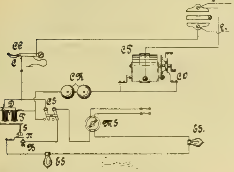

Fig. 14.

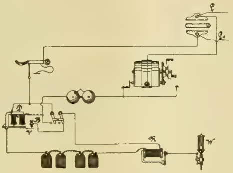

Fig. 15.

AUXILIARY SIGNALS AS APPLIED TO THE TELEPHONE.

In response to an electric current flowing through the magnet D, the armature T, equipped with the spring V, is drawn upward with a slight vibratory motion, making a contact with point B, and thus closing the local circuit only so long as the switchboard operator desires to extend the signal. On first thought it may appear to be an easy matter to construct a relay that will successfully close a local bell circuit in response to an alternating current such as is produced by the magneto generator employed in operating telephone apparatus. It can be done by a very simple trick; in fact, an instrument constructed similar to the one shown in Fig. 12 will answer the purpose under the most difficult conditions; however, to the doubting ones—"seeing is believing."

With a direct-current generator located at the central office, a telephone station may be equipped with an arrangement for allowing the exclusive selection of one of three distinctly separate signal-receiving instruments; that is, an alternating current operates the magnet bell C R (see Fig. 13), a direct current, flowing from the line to the hook-switch C C, operates the relay R A, and a direct current flowing in the opposite direction operates the relay R X; any one of the relays when operated closing its respective local-bell circuit. With properly adjusted armatures and contact points, the arrangement as described gives a very satisfactory service.

Fig. 14 indicates a method of substituting an incandescent lamp for the electric bell shown in Fig. 11. A tap from the lighting mains takes the place of a local battery. The method, though it gives a fairly satisfactory service, is not to be recommended, mainly on account of the danger from fire that an imperfect contact at T B might produce.

Fig. 15 represents an electro-magnet substituted for the electric bell shown in Fig. 12; the armature of the electro-magnet, being permanently connected to the valve of a steam whistle, enables an operator at the central office to produce a call signal that usually results in an immediate response. The device is capable of rendering a very effectual signal; for obvious reasons, however, the plan should be adopted only as a last resort.

Some years ago licensees of the Bell company were put to considerable bother in removing from the subscribers' telephones a little attachment sold and put up by traveling agents. The device consisted of a movable disk arranged with trip, its upper end-prong engaging the rod bearing the tapper of the magneto bell. When properly adjusted and kept so the device served admirably, but soon it was discovered that the addition of a small contact pin would allow the closing of a local bell circuit whenever the disk fell. Naturally, the transmitter battery was pressed into service, with the usual disastrous results, which, of course, led to a speedy removal of all such attachments.

Realizing that many novel arrangements have been designed and are giving successful service as extension signals, the writer would suggest that it might be of interest to know just how much ingenuity has been expended in supplying the actual, and at times, perhaps, the imaginary, needs of our friend the telephone subscriber.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The offices of the Iowa Telephone company have been consolidated at Davenport. There was talk of removing all of them to Des Moines, to be nearer the central part of the state, but after a trial of part of the offices in Des Moines, it has been decided to remove them all back to Davenport.

Work will be begun soon on the line of the Humeston Telephone company at Humeston, Ia.

The Woodbine Telephone company expects to have a line to Mapleton, Ia., from Onawa, Ia., in 60 to 90 days. Connections may also be made with Ute.

Rev. H. E. Walker of West Concord, Minn., contemplates establishing a telephone exchange in Hankinson, N. D. He has gone to look over the field.

Arrangements have been made to extend a telephone line to Rodney, Ia., connecting Oto and Smithland. Rodney people want the line extended to Onawa.

A. B. Tallman, president of the Crookston, Minn., Telephone company, has disposed of his interest to residents of Crookston.

F. G. Barrows has been granted a franchise for a telephone exchange for Fergus Falls, Minn.

C. J. Smallwood has been granted permission by the council of Worthington, Minn., to establish a telephone exchange.

The 100-wire cable of the Oshkosh Northwestern Telephone company at Oshkosh, Wis., crossing the Fox River, was broken, cutting off the south side of the exchange. It is supposed the break was made by the Citizens' Traction company in sinking a feed cable. The company will put in a new cable at once.

Arrangements are being made by the Ottumwa Telephone company and the Moravia Telephone company to connect, by building to Blakesburg. This would give a big improvement to the Centerville connections.

The New Ulm, Minn., Telephone company is arranging to extend its lines to Redwood Falls, Minn., from Sleepy Eye through Evan, Morgan and Gilfillan.

The American Telephone and Telegraph company will connect with New Richmond, Wis.

The Janesville Telephone company has been incorporated at Janesville, Wis., with $25,000 capital stock.

The Hyde and Orton Telephone company of Princeton, Mo., contemplates establishing a telephone exchange in Centerville, Ia.

The Chamber of Commerce in St. Paul has passed resolutions urging the council to grant a franchise for long-distance telephone service.

A farmers' telephone line has been built from Harmony, Minn., to Kendallville, Ia., and proposed to go to Cresco. The mayor of that town demands a tribute before he will allow the company inside the corporation. He raises the legal point that the company is not incorporated.

Northwood, Ia., people complain of the service they receive from the Iowa Telephone company.

Gregg & Dixon and the Central Telephone company of Rockwell City, Ia., will consolidate their exchanges and put in additional capital.

Otis Staples, James Mulvey and R. H. Bronson have been granted a franchise at Stillwater, Minn., for a telephone exchange.

J. J. Greaves has ordered a 50-drop switchboard for a local exchange at Glencoe, Minn.

The local telephone company of New Richland, Minn., will secure long-distance connections over the wires of the Western Electric Telephone company.

The Mississippi Valley Telephone company has deposited $5,000 in St. Paul as a guarantee that it will accept the franchise recently granted. The ordinance also provided for a bond for $25,000 within 30 days of its passage.

The Minnesota Central Telephone company will begin stringing its wires into Minneapolis soon, as far as the conduit limit. The Mississippi Valley Telephone company will have to lay conduits in all the downtown streets before it can install an exchange. It is probable the Minnesota company will use the Mississippi Valley company's conduits.

The Marquette County Telephone company will soon begin extending its system from Ishpeming, Mich., to Humboldt, Republic, Champion and Michigamme.

H. H. Heath of Neillsville, Wis., will establish a telephone exchange in Greenwood, Wis., as part of his system, connecting Marshfield, Neillsville and Merillan.

The Perry Telephone company is building a line from Guthrie Center, Ia., to Panora, and expects to build to Audubon. The Iowa Telephone company first came to Guthrie Center and secured subscribers for an exchange, but did nothing until the Perry company secured a franchise. Since then the proposition of the Iowa company for a franchise has been rejected by vote of the people.

D. A. Kusel.

The portrait presented herewith is an excellent likeness of D. A. Kusel, proprietor of the D. A. Kusel Telephone and Electric Manufacturing company of St. Louis, Mo., an experienced electrician well known in the West. He has been engaged in the electrical manufacturing business in St. Louis and Chicago for the last 30 years. He has been a resident of St. Louis for 20 years and established his present business in 1886 for the manufacture of general electric goods, but since the expiration of the Bell patents in 1893 he has devoted his whole

D. A. KUSEL.

attention to the manufacture of telephones and telephone switchboards. He is the patentee of the D. A. Kusel transmitter, which has gained a wide and favorable reputation over a large portion of the country. His wide and thorough experience in this line enables him to superintend his factory with great advantage to the patrons of the company.

Extension of Independent System in Wisconsin.

The Little Wolf River Telephone company has closed a contract with the Oshkosh Northwestern Telephone company, whereby the local exchange is to be connected with the toll system of the Wolf River Telephone company, already in operation in parts of Winnebago and Waupaca counties. The contract calls for connecting the two systems by June 1st. The line, as projected from Fremont, where it ends at present, will run through Dale, Winchester, Larson, Allenville, Butte des Morts, Winneconne, Omro and thence to Oshkosh. A great many of these towns have at present no telephone system, and much of the trade from these points comes to Oshkosh.

At present the Wisconsin Telephone company charges a rate of 25 cents for Oshkosh residents who desire to talk with towns in Waupaca County, and to points in Winnebago County 20 cents. The toll rate of the Northwestern exchange will be to

cents to points in Winnebago County and 15 cents to Waupaca County points.

Immediately after the extension from Fremont to Oshkosh is completed, another extension from Larson to Neenah, Menasha and Appleton is to be made, followed by another from Symco, in Waupaca County, to Antigo, running through Bear Creek, Clintonville, Embarrass, Hunting, Marion, Split Rock, Tigerton, Whitcomb, Wittenberg, Eland Junction, Mattoon, Elmhurst. No telephone lines at present touch these points, and Oshkosh patrons of the Northwestern company will be enabled to talk direct with these points for a nominal sum. The line is already built from Symco through Manawa, Little Wolf, Royalton, Northport, New London, Weyauwega, Waupaca, Fremont, Orihula, Alder Creek and Tusten.

Independent Long-distance System for Indiana.

The movement for an independent long-distance telephone system in Indiana, with headquarters at Indianapolis, has resulted in the formation of the New Long-distance Telephone company, with a million dollars capital, by A. H. Nordyke of Indianapolis; Daniel E. Doherty of Louisville, Ky.; Alexander F. Ramsey of Crawfordsville, Ind.; George W. Beers of Fort Wayne, Ind.; Harry B. Gates, Simon P. Sheerin and David M. Parry of Indianapolis. The incorporation fee was $1,002, the largest that Secretary of State Owen has received for some time. It is understood that the gentlemen named are to be the directors of the organization, and that Mr. Sheerin is to be the president, Mr. Ramsey the vice-president, Mr. Nordyke the treasurer and that the secretary has not yet been elected.

Concerning the new corporation, Mr. Sheerin is reported to have said: "This organization has been in contemplation for some time, and may be said to be already perfect in all its parts. It has been the intention of the gentlemen composing the New Telephone company to build sufficient long-distance lines to connect with Indianapolis all the independent long-distance lines now operating in the state and such other lines as may hereafter be constructed. We were not at first clear as to whether we would form a separate organization and increase the capital stock of the Indianapolis company to an extent sufficient to embrace the other work. The action of the Board of Works, however, in limiting the capitalization of any company bidding upon the franchise in this city settled that question for us, and we then determined upon the separate organization. All of the gentlemen interested in the New Telephone company are interested in the one just incorporated.

"We will begin at once and will have the long-distance lines in operation long before the work in this city can be completed. A good deal of long-distance business can be done by special-messenger service in the city until such time as the exchange is ready for operation."

The Indianapolis Sentinel says that it is understood that Mr. Beers, who is a practical electrician and experienced telephone man, is to superintend the construction of the long distance lines. Mr Beers is the president of the Home Telephone company of Fort Wayne and also of the National Long-distance Telephone company, which operates about 1,000 miles of long distance lines in the northern and eastern part of the state.

Mr Ramsey is president of a long distance telephone line in the western part of the state, with headquarters at Crawfordsville, which controls about 600 miles of long distance lines.

The Sentinel also announces that several other gentlemen interested in long distance telephone business in different parts of the state have become member of this long-distance telephone company.

Southern Iowa Telephone Service.

Charles McFatridge, manager of the Moravia, Ia., Telephone company, proposes to extend the Moravia system to Blakesburg, providing that Manager Martin of the Ottumwa company will build a line to that city. In this event Manager McFatridge promises to extend the Moravia line to Confidence, and through such a combination Centerville would secure telephone connections with the following towns in southern Iowa and northern Missouri touched by the consolidated companies: Mystic, Seymour, Promise City, Confidence, Allerton, Warsaw, Lineville, Davis City, Kellerton, Ellston, Mount Ayr, Caledonia, Clearfield, Lewisburg, Humeston, Groveland, Bethlehem, Des Moines, Brazil, Numa, Mardensville, Bridgeport, Ovid, Harvard, Clinton Center, Spring Valley, Lamoni, Lesan, Tingley, Maloy, Ringgold, Conway, Smiths, Weldon, Osceola, Indianola, Lorimer, Jerome.

THE "LITTLE HUSTLER" FAN MOTOR.

Genoa, New York, Corydon, Cambria, Sewall, Clio, Pleasanton, Tuskega, Beaconsfield, Benton, Wanamaker, Leon, High Point, Garden Grove, Leslie, Ravenna, Mo., Andoar, Princeton, Bethany, Powersville, Burlington, Marysville, Unionville, Albany, Cainesville, Modena, Mercer and Ader.

The scheme has received the endorsment of the principal telephone men of the towns named and has enlisted the enthusiastic support of the merchants of these places.

Independent Telephony in Southwest Missouri.

Three years ago the first indepdent telephone line was built from Humansville to Hermitage, a distance of 25 miles. This was the beginnng of the system, which to-day comprises over 400 miles of toll lines, with 71 toll stations, nine of which are county seats—Sedalia, Clinton, Warsaw, Osceola, Hermitage, Buffalo, Bolivar, Stockton and Greenfield.

CARD GENERATOR.

Four companies support the system, including the Hull Telephone company, with headquarters at Humansville, the St. Clair County Telephone company, whose main office is at Appleton City, the Russel Telephone company of Brownington and the Taylor Telephone company at Greenfield.

The Taylor company is now building to Mount Vernon, and will there intersect the Armstrong lines, which will add over 200 miles to the independent telephone systems of Southwest Missouri. Most of the stations reached in this system have a population of less than 4,000, and the Bell people have been slow in providing service for them.

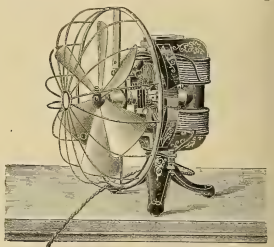
Most of the leading citizens in this territory are interested in the home companies.

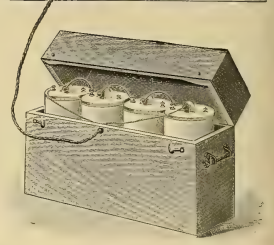
The "Little Hustler" Fan Motor.

As the cut shows, this is a small fan motor, battery driven. It is sold at a remarkably low price, and yet is said not to be a toy but a correctly designed motor for commercial use. It can be used in connection with any suitable type of battery. This motor is made by the Knapp Electric and Novelty company of 47 Warren street, New York.

Card Generator.

The 225-kilowatt generator illustrated herewith is the latest design brought out by the Card Electric company of Mansfield, Ohio. Every part of the machine, while massive, is well proportioned and made to withstand hard work and rough usage. The armature has some special features in the way of conveniences for ready inspection and repairs which will be appreciated by purchasers. With the winding on this armature it is possible, by unsoldering not to exceed 12 connections at the commutator, to remove any coil from it without disturbing





NEW EDISON FAN MOTOR.

any other coil in the body of the armature. This the company will guarantee. The provisions for uncovering the armature are both simple and effective. By means of the screw and lever on the base-frame the two supporting bearings and armature are forced rearward or the base until the armature body is in the place of the pulley and the commutator completely uncovered; in this position any of the field coils can be removed. A reverse movement of the screw returns all of the parts to their proper place. With heavy windings, a large commutator and improved brush-holders, this generator is well fitted for any kind of heavy duty, and the company reports a large number of recent sales, which keeps it busy night and day.

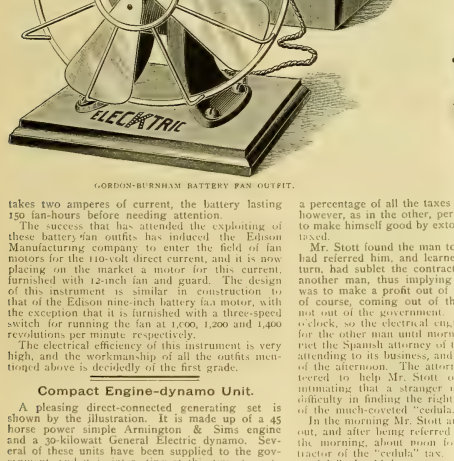
New Edison Fan Motor.

Several new battery fan-motor outfits are being placed on the market by the Edison Manufacturing company of New York and Orange, N. J. The Edison nine-inch battery fan outfit is shown in the cut. This outfit is furnished with a motor having a Paccinoti ring armature, carrying a nine-inch fan and guard, and operated by four Edison-Lalande cells, type "S" (300 ampere-hour capacity), in polished oak box, together with battery cord. The motor is now provided with ball bearings, and the results that have been obtained by this innovation are so remarkable as to call for a detailed description.

When this outfit was first placed on the market, four or five years ago, the motor was of the six-pole armature type, and ran for about 100 fan-hours, at a speed of 700 revolutions per minute, before the battery needed to be recharged. In the spring of 1897 this motor was entirely redesigned, being replaced by one having a Paccinoti ring armature. The immediate results were very gratifying to the manufacturers, as the working current was de-

creased so that the battery would now run the fan for 125 fan-hours before needing renewal, and the speed of the motor was increased to 800 revolutions per minute. In order to further increase the efficiency of this motor, the use of ball bearings was finally decided on, after a most exhaustive test extending over several months; and the results that are now obtained fully justify the innovation which has been made. The frictional loss has been so greatly diminished by this means that the new ball-bearing motor (1898 model) only takes 1.75 amperes when running the fan, and as the battery has a capacity of 300 ampere-hours, it follows that the motor will run 170 fan-hours before the battery is exhausted. The speed of the fan is also increased to 850 revolutions per minute. It is interesting to compare the successive steps which have been made in the perfecting of this motor. Considered from a battery point of view only, the new ball-bearing motor is 33½ per cent. more efficient than the 1897 model and 70 per cent. more efficient than the original type. Furthermore, the speed of the fan is increased from 700 revolutions per minute to 850 revolutions per minute, which is even more important than the economy that has been effected in the battery.

The Edison iron-clad battery-fan outfit, manufactured by the same concern, has also been considerably improved this season. It consists of an iron-clad motor, carrying a seven-inch fan and guard, and operated by three Edison-Lalande cells, type "S," in polished oak box. The improvement consists in the substitution of a small drum commutator for the flat-disk commutator, which was formerly used on these motors, and the extension of the rear shaft support (carrying the brushes) beyond the iron-clad field, thereby enabling the brushes to be easily and quickly adjusted. This motor runs at a speed of 1,200 revolutions per minute, and



GORDON-BURNHAM BATTERY FAN OUTFIT.

takes two amperes of current, the battery lasting 150 fan-hours before needing attention.

The success that has attended the exploiting of these battery fan outfits has induced the Edison Manufacturing company to enter the field of fan motors for the 110-volt direct current, and it is now placing on the market a motor for this current, furnished with 12-inch fan and guard. The design of this instrument is similar in construction to that of the Edison nine-inch battery fan motor, with the exception that it is furnished with a three-speed switch for running the fan at 1,000, 1,200 and 1,400 revolutions per minute respectively.

The electrical efficiency of this instrument is very high, and the workmanship of all the outfits mentioned above is decidedly of the first grade.

Compact Engine-dynamo Unit.

A pleasing direct-connected generating set is shown by the illustration. It is made up of a 45 horse power simple Armington & Sims engine and a 30-kilowatt General Electric dynamo. Several of these units have been supplied to the government, and it is interesting at this time to note that two furnish current for the United States forts at Castle Island, Boston Harbor. The engine has cylinder dimensions of 9½ by 10 inches, and operates at about 300 revolutions per minute. It is equipped with the Rites inertia governor, self-adjusting piston valve and special oiling devices.

Gordon-Burnham Battery Fan Outfit.

The Gordon-Burnham Battery company of New York has received so many urgent requests asking for a combination which should include its Gordon primary cell and a fan motor that it has decided to furnish the outfit desired, and accordingly has made arrangements to provide the Knapp battery motor, which has been long in use before the electrical trade, using the 1898 models and recommending types C and D, which have ball bearings and are very efficient. The Gordon-Burnham company will also exclusively handle the Knapp motor B2, C2 and D4. The long life of the Gordon primary cell is known in the electrical trade, and the company's guarantee to operate at a good discharge rate for six months without any attention gives to the electrical trade a battery well fitted for fan-motor work. The economy of maintenance of the Gordon cell is also a great advantage.

Spanish Business Methods.

H. G. Stott, superintendent of the Buffalo General Electric company, tells a story of his experience in Madrid. Some few years ago, before he came to America, he was employed by an English company, which had a contract to establish an electric-lighting plant in Madrid, and he was sent there as the representative of the company. Before he went he was informed that all foreigners, before they attempted to do business in Spain, were obliged to take out a government license, nominal in amount, called the "cedula." It was early afternoon that he arrived in Madrid, and as soon as he had settled himself at the hotel, he started out to find the government office where he was to take out his "cedula." He found the office, but, on applying for his permit, he was told that the government had "farmed out" the cedula tax to a certain individual, and that it would be necessary to look this individual up.

Now in Spain the farming out of a tax means one of two things; either that the government sells the collecting of the tax to some individual for a sum as great as the government expects to secure from the tax for the year, the government tacitly admitting the individual's right to make his speculation good by raising the amount of the tax on the persons taxed, or in some cases, the government sells the collecting of the tax for a fixed sum and a percentage of all the taxes collected; in this case, however, as in the other, permitting the tax farmer to make himself good by extortion from the persons taxed.

Mr. Stott found the man to whom the government had referred him, and learned that this person, in turn, had sublet the contract for the collection to another man, thus implying that some one else was to make a profit out of the tax, all this profit, of course, coming out of the persons taxed, and not out of the government. It was now about six o'clock, so the electrical engineer gave up looking for the other man until morning. That evening he met the Spanish attorney of the company, who was attending to its business, and related his experience of the afternoon. The attorney smiled and volunteered to help Mr. Stott on the following day, intimating that a stranger might still have some difficulty in finding the right man for the issuance of the much-coveted "cedula."

In the morning Mr. Stott and the attorney started out, and after being referred from man to man all the morning, about noon found the last sub-contractor of the "cedula" farm. Good to law the "cedula" should have cost about two pesetas, or 40 cents. When Mr. Stott started to pay he was amazed to have the tax farmer calmly demand 20 pesetas, or about $4. This extortion aroused the ire of the attorney, and he went for the tax farmer. After an oration of half an hour, five pesetas were thrown off, making the price about $3. This encouraged the attorney and he started in again, the result being that three more pesetas were dropped, making the tax about $2.40, which Mr. Stott paid, feeling his company could better afford paying this amount of tax instead of the ball the attorney was likely to present. The result justified his foresight.

"The Spaniards have no real idea of public honesty," said Mr. Stott. "Poverty is the general condition of the laboring classes; poverty of a kind this country knows little about, and yet no one hesitates to take advantage of the most miserable of these creatures. We could not prevent foremen of the construction gangs from robbing the workmen under them. They would bleed them of a portion of their miserable wages, and no matter what we paid, the foreman got the greater part of it.

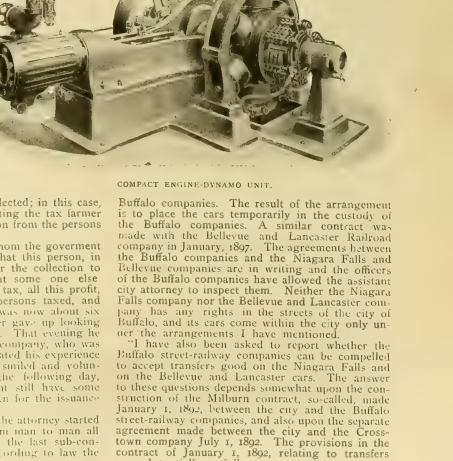
"We could not employ Spaniards to read meters, after the company began to supply light, for they would invariably go to the consumer and make an arrangement to turn in a short reading for a given consideration. A Spaniard of high respectability told me that he never thought of paying what his gas bills properly came to. He gave the meter-reader four or five pesetas a month and the fellow cut the reading down enough to save him three or four times the amount. Our contract was to put in the electric-lighting plant and run it six months, which we did. At the end of that time the Spanish company which was to manage it offered me double the salary I was getting from the English company and a three years' contract, if I would stay and manage the plant. But I was utterly disgusted with the Spaniards. I had had enough."

Street-railway Companies' Rules and Regulations.

An opinion of interest to trunk-line trolley companies was recently given by Corporation Counsel Cuddeback of Buffalo on the question of whether the Niagara Falls and Lancaster roads should be compelled to accept transfers on their lines, and also as to the rights of these companies to operate their cars within the city limits. The opinion is as follows:

"I have been directed by your honorable body to ascertain and report what rights the Niagara Falls railroad cars and the Bellevue and Lancaster cars have in the streets of the city of Buffalo.

"I find that in November, 1893, an agreement was made between the Buffalo street-railway companies and the Niagara Falls company, which was modified in May, 1897; and that by the provisions of the agreement, as modified, the Buffalo companies take the cars of the Niagara Falls company at the city line and run them over the tracks in the city and return them to the Niagara Falls company at the city line. While within the city the cars and the crews thereon are entirely within the control of the



COMPACT ENGINE-DYNAMO UNIT.

Buffalo companies. The result of the arrangement is to place the cars temporarily in the custody of the Buffalo companies. A similar contract was made with the Bellevue and Lancaster Railroad company in January, 1897. The agreements between the Buffalo companies and the Niagara Falls and Bellevue companies are in writing and the officers of the Buffalo companies have allowed the assistant city attorney to inspect them. Neither the Niagara Falls company nor the Bellevue and Lancaster company has any rights in the streets of the city of Buffalo, and its cars come within the city only under the arrangements I have mentioned.

"I have also been asked to report whether the Buffalo street-railway companies can be compelled to accept transfers good on the Niagara Falls and on the Bellevue and Lancaster cars. The answer to these questions depends somewhat upon the construction of the Milburn contract, so-called, made January 1, 1892, between the city and the Buffalo street-railway companies, and also upon the separate agreement made between the city and the Crosstown company July 1, 1892. The provisions in the contract of January 1, 1892, relating to transfers are substantially as follows:

"The companies agreed to abolish all transfer charges after January 7, 1892, and thereafter to charge a uniform fare of five cents for a continuous trip by the most direct route from any point on any of the street railroads owned and operated by said companies to any other point thereon, to the end that there should be a uniform five-cent fare for a continuous trip to any point by the most direct route over any portion of the railroad system operated by the companies.

"By the agreement of the Crosstown company the provisions of the Milburn contract are applied to that part of the street railway running on Broadway between Bailey avenue and the city line. The Crosstown company by its agreement is also made subject to section 101 of chapter 565 of the laws of 1895, which prohibits the company from charging any passenger more than five cents for one continuous ride from any point on its road or any road,

line or branch operated by it or under its control, to any other point thereon, or any connecting branch thereof.

"There is no doubt that under these contracts and under the statute referred to, the street-railway companies have the right to adopt reasonable rules and regulations to facilitate their business and prevent imposition in the matter of transferring passengers from one line to another.

"I understand that the street-railroad companies refuse to give transfers to the Bellevue and Lancaster cars and refuse to accept Niagara street transfers on the Niagara Falls cars. The attorneys for the street-railroad companies inform me that these cars are intended primarily for through traffic, that is, for passengers who wish to go to Niagara Falls or to Lancaster or to points beyond the city line. The only question is whether it is a reasonable regulation to refuse to give or accept transfers upon these through cars. It seems to me that it is a reasonable regulation and quite as much to the advantage of the public as of the railroad company, provided always that the railroad companies furnish other and sufficient accommodations for local passengers. So far as street railways are concerned I think there are not many decisions upon the question by the court, but the same question has frequently arisen in regard to steam railroads, and the right to make and enforce reasonable regulations has been upheld. The street-railroad companies must, of course, comply with their contracts and with the statute, as reasonably interpreted. Their obligation is to charge only five cents for a continuous trip by the most direct route from any point on any of the street railroads owned and operated by them to any other point thereon. If they furnish a sufficient number of cars so that there is no vexatious delay in transferring passengers, may not also run through cars, and, to prevent overcrowding, restrict the use of them to through passengers? It would seem that they may, for the same reason that steam-railroad companies are allowed to run through trains and fast express trains which do not stop either to take on or let off passengers at way stations. If the street-railroad companies are held to their obligations to run sufficient cars to accommodate traffic within the city, the necessity of the public will be satisfied and no harm will come if the companies are allowed to operate what have been called through cars over their lines.

"It should always be understood when I say a rule or regulation of a street-railroad company is reasonable that I am simply exercising my judgment as to what the courts would probably hold in regard to such rule or regulation, and that the expression of my own opinion goes no farther than that.

"There is another question that I might as well answer in this communication. A petition by the residents on Tonawanda and other streets at Black Rock, asking that the street-railroad companies be compelled to run cars on Hertel avenue and Tonawanda street to the city line all night, and to use large vestibuled cars upon that portion of the line, has been referred to me.

"The grant from the city to the Crosstown Railroad company to operate the line in Tonawanda street gives the council full power in the matter, but, of course, the power must be exercised reasonably. I do not know enough about the situation to say whether the prayer of the petition should be granted, but if it is necessary for the accommodation of the public that cars should run all night on the city line on Tonawanda street, and that better cars should be used, then the street-railroad company should be compelled to comply with the petition."

WAR NEWS.

[*Continued from page 255.*]

United States Army in time of war by organizing field-telegraph corps.

A correspondent at Matanzas sends word that the steamship Vigilancia was driven from the harbor on Thursday night (April 21st) in order that the harbor might be mined. It is in such condition now that it would be perilous for any vessel to enter the harbor, and the Spanish authorities have made arrangements to notify any ship that sought to enter, save those belonging to the United States.

They have curious dynamos in Havana, if the correspondents are to be believed. It is said recently an electric-light dynamo exploded in the navy yard there, blowing off the head of an employe and seriously wounding the foreman of the shop and 10 workingmen.

Chicago street-car men are to be given an opportunity to go to the front. General Manager John M. Roach of the North Chicago and West Chicago Street Railroad companies has ordered a notice posted to state that enlisted men or those who volunteered for war service would be granted leave of absence and that their positions would be held for them when they returned. Superintendent Nagle of the Chicago City Railway company said that the employes of that company would fare similarly.

The New York Herald claims to have established a pictorial telegraph department to its already well-equipped newspaper plant. It recently sent the necessary transmitting apparatus to Key West, Fla., and since its arrival there the Herald has been presenting daily to its readers pictures said to have been transmitted by telegraph. The distance to be traveled by these pictures is about 1,500 miles, of which 160 miles is submarine cable. The time of transmission of a half-page drawing is stated to be 40 minutes.

When the regulars moved south from Fort Sheridan, near Chicago the signal corps took 10 miles of wire, 500 line supports and three wagons loaded with batteries and instruments as its equipment. The rough hills of Cuba are expected to prove formidable obstacles to the work of the signal corps, but its members declare that they can overcome even mountains and swollen rivers in their work.

The Eastern Extension Telegraph company announces that, with a view to improving telegraphic communication with the Phillipines by making such communication independent of the long land line between Cape Bolinao and Manila, it has extended the cable from Hongkong to Manila direct.

A Paris letter of April 23d says that a considerable number of electrical engineers engaged by the Spanish government left Paris on the day before for Ferrol.

National Electric Light Convention, Chicago, June 7th, 8th and 9th.

The most popular line from Cincinnati, Louisville and all points South to Chicago is the Big Four Route via Indianapolis; magnificent sleeping cars and unequaled dining-car service. For maps, rates, etc., address E. O. McCormick, passenger traffic manager, Big Four Route, Cincinnati, O.

CORRESPONDENCE.

New York Notes.

New York, April 25.—As the time draws near for the electrical exhibition the interest is increasing, even amid the war excitement. A lately arranged feature is a series of eight illustrative and historical wax tableaux, designed to mark some of the successive stages of electrical development, prepared by Dr. Park Benjamin, Prof. F. B. Crocker and Mr. F. C. Martin, and executed and arranged by the Eden Musee company. The series will include the "First Recognition of an Electric Effect," when the Syrian woman, many centuries ago, wonderingly perceived light objects flying to her amber spindle; the "Mariner's Compass," ascribed to the Chinese and Italians, but probably to be credited to the Finns, in the eleventh century; "The Earth a Great Magnet," William Gilbert explaining the terella to Queen Elizabeth, 1600; the "First Conductors or Circuits," Stephen Gray, a Charter House pensioner in London (1720), experimenting on the conduction of electricity; the "Leyden Jar," showing the "botting" of electricity and the terrible shock to Dean Von Kleist, canon of the cathedral in Cumin, in Pomerania, 1746; "Identity of Lightning and Electricity," representing Benjamin Franklin performing his celebrated experiment of 1752; "Beginnings of the Battery," Galvani's "Voltaic Cell," with Galvani's famous frog experiment, 1791, and the "Beginnings of Modern Dynamo-electric Machinery," showing Michael Faraday's famous experiment, 1831. These tableaux are accompanied by a descriptive lecture by Dr. Park Benjamin on the early philosophical, technical and electrical books, each illustrating some feature or stage of electrical evolution.

Another feature will be an exhibit of the work of the students of the Hebrew Technical Institute, including a small electric-lighting plant complete and shown in operation in lighting a small house. Mr. Charles Chamberlain has been placed in charge of the gas features of the Electrical Exhibition.

In consequence of the illness of Prof. Sidney H. Short, and the fact that so many of the members of the society are engaged in active work on the electrical exhibition, it has been decided to give Prof. Short's lecture on "The Outlook of High Electric Traction" during the exhibition next month. At the electrical exhibition there will be various demonstrations of scientific phenomena and principles by means of models and apparatus, which will be in more or less continuous operation. As the society has been entrusted with a great deal of the work of this kind, it would like to secure from among its members the help of volunteers to take charge of various features for a time, so that the duty will not be heavy, but will be made as light as possible. The first applications will be selected, preference being given, as far as possible, in case there are a large number of applications, to students of educational institutions. The assignment to duty will be in the hands of a committee of the society and the Exhibition company, and the work of such members will be publicly recognized.

The Long Island Railroad company has made arrangements to give electric service during the time that the East River tunnel is being constructed. A contract has been entered into with the owners of the Brooklyn elevated railroad to run a through service from Coney Island over the surface lines of the Long Island railroad and the Fifth Avenue line of the Brooklyn elevated railroad to Brooklyn bridge. The elevated road at the Flatbush avenue station will be connected with the terminal of the main line running to Jamaica, giving through service to this route. Another line will be equipped running from Jamaica and Rockaway Beach by way of East New York and the Broadway line of the Brooklyn elevated road to the Broadway ferry. The tracks of the elevated road will be extended over both the Brooklyn bridge and the bridge now building.

It is possible that the streets in the borough of Queens may be left in darkness before many days. The contracts for street lamps are expiring and the city has so far declined to recognize the many contracts rushed through for electric lighting in the last days of the year. The only contract for electric lighting so far approved is that for Long Island City, which calls for $78,800 a year. Flushing, College Point, Whitestone, Hollis, Far Rockaway, Arverne, Rockaway Beach, Jamaica and other villages will have to do without street lights. The estimated cost of lighting the entire borough is $400,000 a year, and the Board of Estimate and Apportionment has rejected the estimate.

The Metropolitan Street Railway company is experimenting with compressed-air motor cars, designed to run indifferently over horse, cable or electric-railway tracks.

W. F. O.

PERSONAL.

The many friends of W. L. Arnold, both in Chicago and his old home, St. Louis, will be interested to know that he has recently accepted with the Siemens & Halske Electric company of America the position of district sales agent, with headquarters in the Monadnock block, Chicago. As is well known, Mr. Arnold represented the General Electric company in St. Louis in a most creditable manner. He severed his connection with that company to push the Arnold power transmission system. Mr. Arnold is a man of many friends, particularly in the West and Northwest, and he cannot fail to prove a most valuable man to aid in carrying out the present aggressive policy of the Siemens & Halske company.

ELECTRIC RAILWAYS.

The Springfield (Mass.) Electric Street Railway company has petitioned the railroad commissioners for authority to issue $300,000 additional capital stock to extend and rebuild the lines.

The Peekskill Traction company has been incorporated to operate a 12-mile electric freight and passenger railroad in Westchester County, New York. The company is capitalized at $150,000.

The corporation of Manchester, England, has, it is said, decided to buy the street railways of the city and work them by electricity on the trolley system. It already possesses an electric-lighting system.

A charter has been issued to the Monongahela Street Railway company of Pittsburg (capital, $30,000). The line will run from the city line on the north side of the Monongahela river, on the Pittsburg and Homestead bridge, to Schenley Park bridge, five miles. The incorporators are J. G. Woods, F. M. Rose, C. T. Marsh, C. F. Farren and W. S. Mitchell.

It is announced that trolley lines will be constructed east and west of Utica, N. Y., which will give a system of rapid transit from Little Falls to Rome, a distance of 40 miles. The Delaware Electric Railway company, which contemplates running a trolley road between Milford, Dover and Woodland Beach, has closed the contract for building the road and work will soon be begun. The road will be 38 miles in length.

A sensation in the receivership proceedings of the Terre Haute Street Railway company was created on April 21st by a circular letter of invitation for a meeting of creditors. The letter is signed by the First National Bank, Stanley Electric company, Western Electric company, American Electrical Works, Illinois Steel company and John A. Roebling's Sons company of Chicago. It is said in the circular that the affairs of the company are much involved and that there is need of an investigation of the cause of this condition. The proposed investigation is to cover the period of Russell Harrison's management.

Electrical features of unusual interest are to be associated with the new equipment of the Lewiston (Me.), Brunswick and Bath railroad. Generators to supply alternating and direct currents simultaneously are to be located in Brunswick, Me., the initial installation being 1,000 horse power. Direct current is to be used at the sections of railroad in and about Brunswick, and the alternating current is to be stepped up to 10,000 volts and transmitted to sub-stations at Lewiston, Bath and Lisbon Falls. Here rotary transformers convert the alternating current into direct current for the feeders. Westinghouse apparatus will be used.

The underground trolley cars on Second and Fourth avenues, New York, are a great improvement on the old horse cars, and are highly appreciated by those who ride in them, but the Sun points out that the speed at which they run, and which is one of their chief attractions, has added a new peril to the lives of pedestrians. Their record of slaughter has not yet begun to equal that of the Brooklyn trolley cars, and the mischief they have as yet done has been confined chiefly to collisions with other street cars and with trucks and carriages, but they are none the less a constant source of terror to the

nervous and the timid. What with them, with the Broadway cable cars, and with the multitude of swiftly darting bicycles which crowd the thoroughfares, the New Yorker who goes on foot has to be every moment on his guard against being knocked down, if not killed.

The efforts of rival trolley lines to secure additional territory in Westchester County, New York, resulted in an open conflict last week, when about 200 men employed by the New York, Westchester and Connecticut Traction company began constructing a double track to connect Mount Vernon, New York city and Pelham Manor. This territory is on the Boston post road, and is better known as "No Man's Land," because of numerous disputes concerning the boundary. The Union Railroad company requires only the strip through "No Man's Land" to connect its lines in Mount Vernon, East Chester, New York, Pelham and New Rochelle. It is said that the Westchester company learned that this was about to be done and that company revived an old franchise, given three years ago, took possession of the post road and began to build just outside the limits of the Manor. A dozen mounted policemen from the Wakefield station ordered the builders to show permits from the Building Department. On the failure to do so six policemen and a roundsman were placed on guard to prevent further operations. The next morning 200 Italians arrived and by night completed 900 feet of track in the territory beyond the jurisdiction of New York city.

TECHNICAL SCHOOLS.

The sixteenth annual catalogue of the Rose Polytechnic Institute of Terre Haute, Ind., has been issued. The course in electrical engineering is described and the apparatus in the plant and laboratory is enumerated. Dr. Thomas Gray is the director of the mechanical and electrical engineering departments, and Frank C. Wagner is the associate professor.

ELECTRICAL SECURITIES.

The annual meeting of stockholders of the General Electric company will be held at Schenectady on May 10th.

The annual stockholders' meeting of the Mexican Telephone company will be held May 11th in New York. Stockholders of record on April 21st will be entitled to vote.

The Albany Railway company reports for the quarter ended March 31st: Gross earnings, $145,584, an increase of $20,227; operating expenses, $96,393, an increase of $2,497.

The Binghamton Railroad company reports for the quarter ended March 31st: Gross earnings, $32,973 and operating expenses $23,688; net earnings, $9,285, an increase of $3,115.

The Edison Electric Illuminating company of New York reports gross earnings for March of $263,975, an increase of $56,105 as compared with the same month last year, and net $113,223, an increase of $18,805. For the three months ended March 31st the gross earnings were $819,163, an increase of $158,190 as compared with the corresponding period of last year, and net $378,186, an increase of $53,216.

The Herkimer County Light and Power company of Herkimer, N. Y., with a capital of $400,000, has been formed by the consolidation of the Herkimer Gas Light company of Herkimer, the United Gas and Electric Light company of Little Falls and the Ilion and Mohawk Valley company of Ilion. The directors are William F. Cochran and Alexander S. Cochran of Yonkers, George E. Weed, Maitland F. Griggs, Thomas E. O'Shea, Henry Stanton, Robert A. O'Shea and James P. O'Shea of New York city, and Thomas Ringwood of Ilion.

MISCELLANEOUS.

The recently organized Union Carbide company of Niagara Falls has made arrangements whereby it will control the entire calcium-carbide output in the United States, the company having practically bought out the carbide companies in the country. It has been incorporated under the laws of West Virginia, with a capital stock of $6,000,000. It is understood that with the exception of three factories all those acquired by the company will be closed, and that the operations of the company in the manufacture of carbide will be centralized. The three factories to be continued in operation are located at Appleton, Wis., Sault Ste. Marie, Mich., and at Niagara Falls. The Niagara Falls plant is to be greatly enlarged and continuous furnaces are to be installed, the work now being in progress. This requires a general overhauling of the plant in all its parts. The officers of the new consolidation are: President, Charles F. Dietrick, New York; vice-president, George O. Knapp, Chicago; secretary-treasurer, A. B. Proal, New York; assistant secretary-treasurer, E. J. E. Ward, Chicago; general sales agent, A. H. Mulliken. All the carbide sold in the United States will be through Mr. Mulliken.

TRADE NEWS.

The Union League Club of Chicago has determined to newly wire its entire building and reconstruct its switchboard. The work will be done by the Chicago Edison company. Mysenburg & Badt are consulting engineers.

The new Illinois Electric company of Chicago has secured the agency for the weatherproof, annunciator, office and magnet wire made by the Crefield Electric Works of Saylesville, R. I. A complete stock of all sizes will be carried.

War talk applies to fan motors, or at any rate to those cleverly advertised by the Central Electric company, which says that its motors constitute "an invincible line of ironclads for hot-weather defense," and that they have "passed through many a siege unscarred."

The bulletins of the Warren Electric Manufacturing company of Sandusky, O., are a credit to the establishment. They are pithily written (as might be expected), clearly illustrated and issued in convenient shape for filing. The Warren alternator is described and its workmanlike simplicity pointed out. The names of users and fac-simile testimonials are also given.

For the first time in its history the Standard Underground Cable company is compelled to do Sunday work at its factory in Pittsburg in order to complete large government contracts for submarine and underground rubber insulated cables, to be used for the purpose of defending the approaches to the various harbors along the Atlantic and Gulf coasts. These cables are to be used in making connection between the land and the submarine torpedoes and mines that are to be operated by electricity. Notwithstanding this large work, the company expects to keep up with its regular orders by continuing to run the factory 24 hours a day.

The many friends of George Cutter throughout the West, and Chicago in particular, will be interested to know that Mr. Cutter is once more in his element, so to speak, in the possession of a fine establishment on Lake street, from which he is now able to carry out his fondest plans along the line of the development of novel electrical specialties. For a long time Mr. Cutter's friends have urged him to aggressively push the development of the business for which he is so well fitted, that is, the production of unique and novel electrical specialties, and from all accounts Mr. Cutter is now in a position to actively push this business for which he is so well fitted.

The Walker company will exhibit at the Madison Square Garden show two of its No. 20-L motors, mounted on truck; one No. 20 L motor, dismantled to show construction; two No. 4-A street-car motors, mounted; one 50-kilowatt belted lighting dynamo, direct-connected to Armington & Sims engine, complete with switchboard; type "S" controllers, assembled and dismantled; railway switchboard, complete with feeder and generator panels; ornamental arc lamps; new Walker recording wattmeter and a large display of photographs of its apparatus. Besides this there will be a complete section of the new underground conduit, with a Broadway car shown in operation.

Eugene Munsell & Co. and the Mica Insulator company of New York and Chicago have completed arrangements with the George Worthington company of Cleveland, whereby the latter becomes distributer of both mica and micanite. The factory includes those of Cleveland and some eight or 10 of the adjoining counties. A large stock of India and amber mica, in the sheet and segments for railway motors, as well as micanite plate, segments, rings, cloth, paper, etc., will be kept to supply the electrical trade in that section. This is an important step in the right direction, and the trade in Cleveland and vicinity will appreciate the fact that this stock has been placed in the hands of so large a company, which has the facilities for making prompt delivery.

Within the last three years the Westinghouse Electric and Manufacturing company has installed over 100,000 horse power of polyphase generators, ranging in size from 10 to 5,000 horse power each. Judging from the orders at present on hand, the Westinghouse company will install more than 100,000 horse power of this type of generators alone during the coming year. A single order now on its books calls for 75,000 horse power. Polyphase motors have also been made in large quantities, ranging from 1 to 500 horse power, two of the latter being for the Niagara Falls Electric Light and Power company, where they are utilized to drive the dynamos for lighting the town, power being supplied to the motors by the 5,000 horse power Westinghouse Niagara generators.

A new catalogue, or rather a new edition of a catalogue, of importance to the electrical trade is that on electric-light supplies, just issued by the Western Electric company. This is a neat cloth-bound volume of 560 pages. It is of very convenient size to handle, the pages being 7¾ by 5½ inches. The arrangement of this catalogue is good; nearly every article listed is illustrated by a marginal cut. The printing and paper are fairly good, and although the type is smaller than is customary, it is legible. The catalogue seems to be full and complete, and a carefully compiled index adds greatly to its value. Prices and code-words are given, with brief descriptions of the articles in many cases. Copies of the book will be furnished to the trade upon application. It is said that the weight of the entire edition is 20,000 pounds.

The Gordon-Burnham Battery company of New York will be in its new quarters on May 2d. The new location is at 594 Broadway, where the company has leased large floor space to accommodate its increasing business. The business of this company is said to have been twice as large in March, 1898, as in March, 1897. The company reports that it finds it a little hard to get a high grade of zinc, which it requires in the manufacture of the batteries, as so much of the metal is taken up by the brass manufacturers in the manufacture of wire material. But, fortunately, it has made a number of large contracts for zinc, which will insure a supply for many months to come. The rapid growth of the Gordon-Burnham Battery company's business since General Manager A. S. Pinkham has been in charge of affairs is a good illustration of what hard work and close application to business will do.

A new firm has appeared at 141 South Clinton street, Chicago, under the title of Cass & Aaron. This institution has a nice shop and is prepared to do repairs of all sorts. Armatures and fields will be repaired and rewound, and commutators will be rebuilt and refilled, and all work will be guaranteed. In fact, the institution is prepared to do every class of electrical repairing and is also in the new and second-hand dynamo and motor business, and will carry in addition to a stock of new and second-hand dynamos and motors, arc lamps and transformers. They will buy, sell and exchange and also stand freight or cartage one way on all repair work, and are equipped to work day and night if necessary. Both Philips C. Cass and Jacob Aaron, the members of the firm, are men and eminently fitted to carry on this business with success. Mr. Cass has traveled on the road for a number of years as expert throughout the West, and Mr. Aaron is also well known in Chicago as a mechanical expert.

BUSINESS.

The Ericsson Telephone company, formerly located at 10 Warren street, New York, has removed to 20 Warren street.

The Dearborn Drug and Chemical Works of Chicago have issued booklets showing the importance of analyzing and treating boiler-feed waters and also the necessity of using good lubricating oils.

The Globe Carbon company's catalogue of carbons for motors, batteries, telephones and lamps is convenient in form, well arranged and handsomely illustrated. The company's factory at Ravenna, O., is said to be the most complete of its kind in the country, and the new catalogue shows several improved battery elements and cells and other specialties.

The Knapp Electric and Novelty company of 47 Warren street, New York, has made arrangements with the Gordon Battery company of Chicago, that city, to provide it with its larger size fan motor, to be used in connection with the Gordon batteries. This arrangement will in no way prevent the sale of the Knapp fan motor separately, and in any quantity that the trade may desire.

The Electric Appliance company has increased its line of enclosed Unique lamps by the introduction of a new enclosed lamp for alternating work. This lamp is giving satisfactory results and gives promise of being equal in every respect to the direct-current enclosed lamps. The Electric Appliance company has all of these lamps burning in its store, and it has been commented on favorably by all who have watched its operations.

The John Stephenson company has just awarded the Sprague Electric company another large contract for Lundell power motors with which to equip its blacksmith and machine shops. Considerable interest is attached to the exhibit of the electric-elevator machine for the London underground railway, which is to be shown at the electrical exposition to be held in Madison Square Garden, New York, commencing May 2d. The Lundell motors of this type are the largest elevator machines ever built, and were made by the Sprague Electric company.

The Lynn Incandescent Lamp company of Lynn, Mass., is said to be the largest and oldest of the companies making a specialty of renewing burned out lamps. The company has the wisest business shown that nine out of 10 of its shipments are to old customers and that five out of eight are to lighting stations. This condition of affairs seems to demonstrate that station managers are appreciating the company's efforts to furnish them with a good lamp at reduced cost and that the company is making it possible and profitable for the station manager to use lamps of higher efficiency and replace them oftener.

One of the specialties of the Holtzer-Cabot Electric company of Boston that is attracting attention is the Ness automatic intercommunicating telephone switch. Intercommunicating systems are convenient, but in the usual manual switches, where the switch must be returned to its normal position

by hand after each call, the frequent omission of this duty on the part of somebody using the instruments resulted in unsatisfactory service. The Ness automatic switch entirely overcomes this trouble, as it is arranged so that the replacing of the receiver upon the hook causes the switch to fly back to its own point. The hook and all the switch connections are mounted upon the door, and provision is made for placing the induction coil and transmitter upon it also. The connections are all wired across to the bottom of the box. This permits opening the instrument up without disconnecting or disarranging any of the parts.

Those in the electrical trade interested in seeing the headquarters of what has been referred to as one of the largest electrical supply houses in the world might do well to drop in and inspect the new headquarters in Chicago of the Central Electric company. This concern arranged early this year to occupy larger quarters, owing to the continued increase in business, and the spacious store on the ground floor extending from 264 to 270 Fifth avenue was selected as most suitable for the growing needs of the company. This commodious emporium for electrical goods has an 80-foot front and extends back as far as 140 feet to an alley, which in size is almost a street. Below the store proper is a cellar, which will be employed as a storehouse, lighted with luxfer prisms and provided with cement floor and good ventilation. It is a storeroom well fitted for the heavier portions of the company's large stock. On entering the door the customer finds himself with the store proper directly in front and an assorted stock room off of the left, with the general offices occupying the best lighted portion of the front of the remainder of the store. The back of the store proper, from which the counter trade will be supplied, is the shipping department, well provided with elevators and other conveniences with which to facilitate in every way the expeditious delivery of goods to drays and wagons in the rear commodious alley. It is, however, really impossible to appreciate the care that has been taken in arranging the different departments of this supply house for executing the plans of the company. Its motto is "Large Chicago stock and promptest shipments." The company expects to have the store in readiness for trade as early as May 1st. Meanwhile business continues and will continue as though there was no change of headquarters in progress.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued April 19, 1898.

602,429. Volve Controller. Arthur E. Colgate, New York, N. Y. Application filed September 19, 1896. Renewed October 1, 1897.

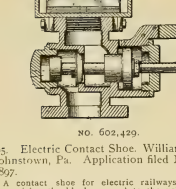
The valve stem is provided with an actuating piston working in a separate chamber and adapted to be actuated by the pressure from the inlet to open the main valve; there are a passage from the inlet to the chamber, an auxiliary valve for controlling the passage, an electromagnet for operating the auxiliary valve, a practically water-tight casing for the magnet, a plate mute and connected tube, through which extends a rod from the armature to the stem of the auxiliary valve, and a packing at the outer end of the tube.

602,434. Signaling Device for Railway Cars. Frank W. Diehl, Detroit, Mich. Application filed September 28, 1897.

The circuit-closing device described comprises a casing adapted to be secured to the car above the heads of the passengers and provided with openings in the top and front, the insulated pivoted contact lever having one end projected through the front opening, the insulated contact plate secured inside the casing in the path of the movement of the lever, the insulated spring for normally holding the lever and plate apart, the circuit wires entering the casing through the top opening and connected respectively to the lever and contact plate, and a cord attached to the projecting end of the lever and depending in reach of the passengers.

602,463. Trolley Wire Hanger. William A. McCallum, Cincinnati, Ohio. Application filed August 16, 1897.

One claim is reproduced: In a line hanger of the character indicated, the combination of the holder, the screw cap having its inner face provided with teeth or corrugations adapted to engage by backward rotation of the screw cap, the insulated bolt seated in the holder and provided with teeth or corrugations corresponding with those of the cap, and the interposed compressible disk.



NO. 602,429.

602,495. Electric Contact Shoe. William M. Brown, Johnstown, Pa. Application filed November 14, 1897.

A contact shoe for electric railways is described, comprising the block secured to the vehicle to be propelled, the hose secured to one side of the block, and the contact strip secured to the hose.

602,527. Electrical Measuring Instrument. Herbert W. Sullivan, London, England. Application filed November 6, 1896.

This instrument has an oscillating coil, a core therefor and magnets in whose field the coil oscillates, having poles with pointed extremities brought into close juxtaposition with portions of the core without interfering with the movements of the coil.

602,557. Alternate-current Meter. Clarence P. Feldmann, Cologne, Germany. Application filed December 21, 1897.

Where there is no direct supply of current to the movable armature, a thin layer of magnetic material is proposed, with the armature of the brake body connected to the same for the purpose of creating a differential effect of such dimensions that a fixed zero position is produced, the sensitiveness of the meter remaining practically unaltered.

602,548. Electric Controller for Gas Regulators. William E. H. Williams and Paul Seiler, San Francisco, Cal. Application filed May 13, 1897.

An electro-magnetic lever is provided for removing the supplemental weight, and an electric circuit extends to a distant point energizing the electro-magnetic devices, and a switch is arranged in the circuit at the distant point, controllable at the will of the operator independently of the gas pressure.

602,564. Insulated Pneumatic Tube. George Peeples, Philadelphia, Pa. Application filed June 19, 1896. Renewed October 5, 1897.

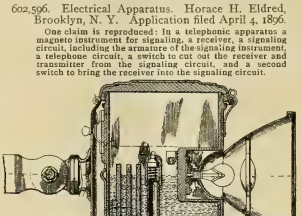
A joint comprising an upper section is connected to but insulated the gas pipe and has notches in its reverse end, a lower section has on its upper face a series of grooves or channels registering with the notches, and means are provided for connecting the two sections together.

602,584. Electric Railway. Hosea W. Libbey, Boston, Mass. Application filed December 10, 1894.

The arrangement includes two rows of parallel alternately arranged bars insulatingly embedded in the cover of a conduit, a supply wire within the conduit, movable conductors between the wire and the bars, and a magnetic trolley, the free end of which is provided with two wheels, one upon each side thereof, and each in electrical connection therewith.

602,596. Electrical Apparatus. Horace H. Eldred, Brooklyn, N. Y. Application filed April 4, 1896.

One claim is reproduced: In a telephonic apparatus a magneto instrument for signaling, a receiver, a signaling circuit, including the armature of the signaling instrument a telephone circuit, a switch to cut out the receiver and transmitter from the signaling circuit, and a second switch to bring the receiver into the signaling circuit.



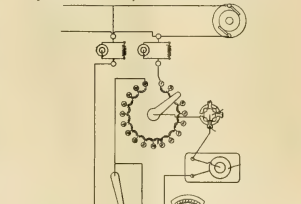
NO. 602,616.

602,616. Invertible Fluid Battery. Porteus R. Cunningham and Charles H. Howland-Sherman, Washington, D. C. Application filed February 20, 1897.

The battery box comprises an open, cylindrical vessel of non-conductive material, formed integrally with a central partition, dividing the vessel into two compartments or cells, an inner chamber or recess, opening exteriorly of the vessel, parallel and vertical spacing ribs projecting interchyl from the walls of the partition and recess or chamber, electrodes fitting between the ribs, the diametrically opposite undercut lugs projecting from the walls of the partition and of the vessel, and clamps engaging with the lugs and with the tops of the electrodes to fasten them in place.

602,667. Railway Switch-operating Mechanism. Charles W. Squires, Springfield, Mass. Application filed November 8, 1897.

The device is electrically operated, the principal feature being the combination with the railway track having the switch and the insulated track section, the return wire and a switch-operating device, of a reversible actuator or engagement member coacting therewith, an electro-magnet and an armature lever, a current conductor in connection with the insulated track section and with a magnet, a current connection running from the magnet to connection with the return wire, and the shifter movably mounted on the armature lever, and bodily movable therewith, cooperating with the actuator to successively reverse it, and an abutment which the shifter engages each time it is reciprocated bodily by the armature lever, whereby its own position is successively reversed.



NO. 602,709.

602,678. Traveling Contact for Underground Electric Railways. Griffin B. Coleman and Joseph W. Duggan, Washington, D. C. Application filed November 2, 1897.

The traveling contact or current collector for underground electric railway systems is claimed in connection with two pairs of lead wires provided with independent couplings and independently connected to the contact shoes of the device.

602,709. Apparatus for Reducing Electric Currents and Voltage. Alexander F. Vetter, Long Island City, N. Y. Application filed September 3, 1895. Renewed November 13, 1897.

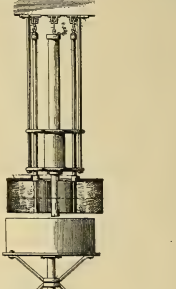
In apparatus for reducing currents and voltage there is the combination with the supply circuit, of resistance controlling the current strength, a second resistance placed in the supply circuit, a shunt circuit including translating devices, and means for transferring a portion of the second resistance of the supply circuit to the shunt circuit.

602,774. Electric Muscular Exerciser. Eugen Sandow, London, England. Application filed January 24, 1898.

The combination is claimed with an elastic cord exerciser, of handles attached to the cords of the exerciser, wires attached to the handles and extending the length of the cords, being so united with the cords as to be capable of extending with them so as not to interfere with the elasticity thereof.

602,746. Street Indicator. Edgar J. Hall, St. Louis, Mo. Application filed November 3, 1897.

This device comprises a dial, a hand adapted to travel over the dial, a spring gearing, a battery, a magnet connected with one pole of the battery, a spring arm carrying an armature over the magnet, a notched disk controlled by the arm and operated by the gearing, a trolley wire provided with a spur, a trolley rod, a plate mounted on the trolley rod, a contact plate and spring pawl mounted on the rod plate and connected with the other pole of the battery and with the magnet.



NO. 602,817.

602,747. Process of Smelting Phosphorus. Charles Knox Harding, Chicago, Ill. Application filed April 5, 1897.

The form of electric furnace may be varied, although the essential features are the same, namely, the tubular cathode located so as to be normally covered by a mass of material to be operated on, the carbon slabs forming the lining of the crucible, the supply of hydrocarbon and the regulating mechanism whereby the arc is governed by automatically controlling the supply of hydrocarbon.

602,767. Electric Switch. Arthur G. McPherson, Highland Park, Ill. Application filed May 1, 1897.

A device for the purpose described has in combination two isolated contacts, each adapted to be connected with one limb of an electric system, a longitudinally shiftable contact piece adapted to connect alternately with the contacts and being in electrical communication with another limb of the system, an oscillatory lever or handle pivoted at a point between the contacts, an elastic connection between the lever or handle and the shiftable piece, and means for retarding the movement of the shiftable piece while in electrical communication with either of the contacts.

602,815. Electric Furnace. George G. Clark, Galveston, Texas. Application filed February 3, 1897.

A revolvable fusing pot is described having an electrical connection therewith, a carbon electrode supported above the pot, and means for automatically drawing or feeding the material inward toward the carbon electrode as the fusing pot revolves.

Western Electrician.
EVERY SATURDAY.
Vol. XXII. CHICAGO, MAY 7, 1898. No. 19

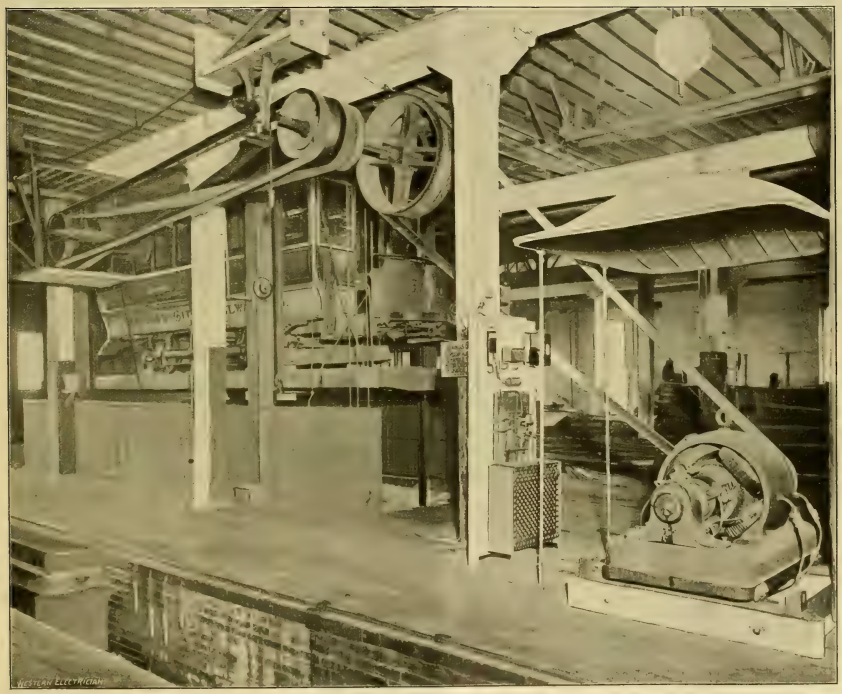
Electric Elevator for Hoisting Trolley Cars.

Modern methods in the management and operation of street-railway properties have introduced many features that were unknown in the days of animal power. For instance, experience has shown that it is economical to establish and maintain a department for frequent inspection of motor cars, and this is particularly true of large corporations, where many cars are in constant service. It is only by systematic effort and close attention that rolling-stock can be kept in first-class condition and the best returns secured from the system.

The introduction of mechanical propulsion on the lines of the Chicago City Railway company directed the attention of the management to this subject at an early day, and that corporation immediately established a machine shop in the old horse-car barns between Twentieth and Twenty-first streets on Dearborn street, back of the office building and power house on State street. The scope and character of this branch gradually expanded until it now comprises one of the best equipped street-railway shops in the country. The entire building is occupied by the mechanical department, and every class of street railway construction and repair work is carried on there. Many labor-saving devices have been introduced, and although the building was not intended originally for such purposes, it has been remodeled and arranged so that, with the aid of modern machinery, excellent results are obtained.

The latest addition to the equipment of these shops is an electric elevator for hoisting and lowering the heavy electric and cable cars. The inspection department and car shops are in the upper part of the building, and the cars that need attention are run in from the street level and hoisted by the electric elevator to the floors above, where they are carefully examined and repaired or cleaned and painted if necessary.

The elevator equipment and the dimensions and capacity of the car are of such unusual character as to attract considerable attention. The picture on this page shows a trolley car of the standard size and weight of those operated by the Chicago City Railway company on the platform of the elevator half-way between the first and second floors. The dimensions of the platform are 10 feet by 31 feet 11 inches, and its carrying capacity is 10 tons. It is operated at a speed of 14 feet 3 inches per minute. It will be seen from the picture, which is a half-tone reproduction of a photograph, that the elevator is constructed in a substantial manner and is well-adapted for this work. It will be noticed that there is a fence built on either side of the elevator shaft to prevent workmen from getting under the car when it is raised to the floors above. This precautionary measure, it is hoped, will prevent accidents such as at the same time keep the enclosure free from all obstructions.



ELECTRIC ELEVATOR FOR HOISTING TROLLEY CARS. VIEW OF APPARATUS EMPLOYED IN CHICAGO CITY RAILWAY COMPANY'S SHOPS.

The mechanical features are simple, and a glance at the illustration will show the method of operation. The elevator equipment is of the standard make of the Eaton & Prince company of Chicago, and the electric motor is a 30 horse power machine built by the Card Electric company of Mansfield, Ohio. It is wound for 500 volts and is operated at 735 revolutions per minute. The field core is cast in one piece, making a perfect magnetic circuit without joints or planed surfaces; the armature shaft is of the best steel, forged within one-fourth inch of the finished size; the armature is slotted, with four-pole winding; the commutator is made of tempered copper, drop forged to gauge, and the armature and commutator are insulated with the best of mica. All bearings are self-oiling and self-aligning. There is no external magnetism; the regulation is automatic, the efficiency high and the point of commutation constant from no load to full load. The rheostat with starting switch is shown in the cut. It is placed at a convenient point so that the operator can see the elevator and be near the motor at the same time.

Mr. E. C. Moore, the master mechanic of the Chicago City Railway company, designed the equipment and supervised its construction and installation. He is well pleased with the results thus far obtained. The elevator runs smoothly and it is believed will prove economical and efficient.

The Western Union Telegraph company has subscribed $5,000 to the stock of the Omaha Exposition, and the Postal Telegraph company has subscribed $1,000 for the same purpose.

Electrical Exhibition in New York.

The opening of the great electrical exhibition now on in Madison Square Garden, New York, took place successfully on Monday night. After an overture by a band, Chancellor McCracken of New York University offered prayer, and then Dr. Pupin stepped forward and requested Dr. Chauncey M. Depew to preside. The opening telegram from President McKinley was in the following words:

"It gives me great pleasure to open the electrical exhibition in Greater New York and to participate in this wonderful demonstration of the latest method of recording and publishing by means of electricity. I congratulate you upon the achievements of American genius. I am glad to know that the resources of the wonderful electrical arts have already been so far advanced in the United States that American electrical goods are welcome the world over."

The exhibition open with the president's telegram, a message was received from Vice-president Hobart, and congratulations were also tendered by the governors of New York and New Jersey. Dr. Depew delivered an oration and Miss Hilks sang "The Star-spangled Banner," the great audience joining in the chorus.

In his address Dr. Depew allowed himself great latitude in his choice of topics. He touched upon the development of electrical science in the last century, and pointed out how much it had done to promote civilization. But before he knew it he was discussing Dewey's victory at Manila, proposing cheers for the commander of the Pacific fleet, for pure plumbago dynamo and motor brushes, in addition to its new arc-light carbons, which are said to be equal to the imported.

The Universal Electric company of New York displays under the supervision of Wood, Shaw & Co. the Universal non-arcing lightning arrester for light and power for direct and alternating circuits.

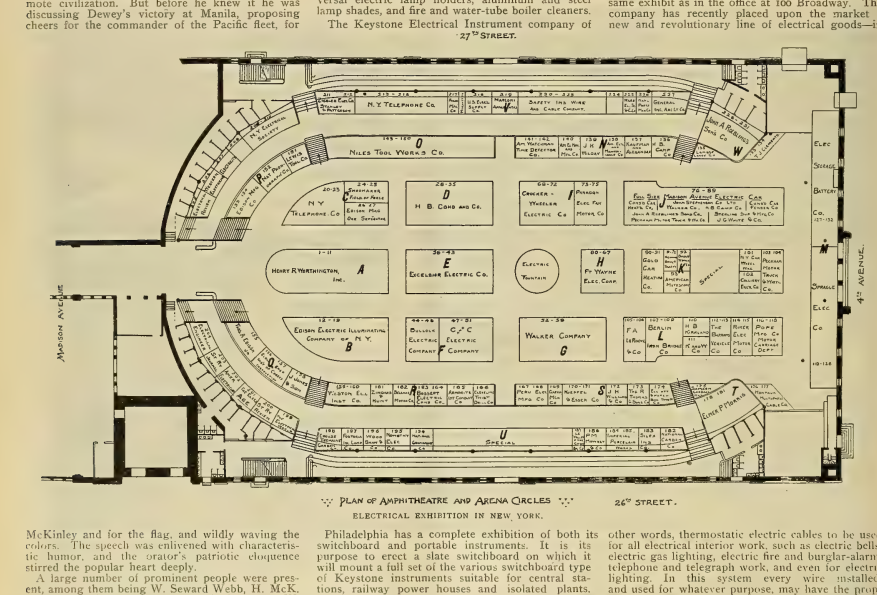
The O. S. Platt Manufacturing company of Bridgeport, Conn., shows the New England snap, indicator, flush, lock and push switches. Its exhibit is made under the supervision of Wood, Shaw & Co.

The Quaker City Electric company of Philadelphia makes a display under the supervision of Wood, Shaw & Co. of its latest designs of generators and motors, in addition to its rheostats and starting-boxes.

The Ward Leonard Electric company exhibits various styles of its automatic magnetic circuit breakers in sizes from a few amperes up to 2,000 ampere size. It also shows a variety of automatic rheostats and several forms of the well-known Carpenter enamel field rheosats.

The Faries Manufacturing company of Decatur, Ill., may be found on the Twenty-seventh street side of the building, on the promenade just above the main floor, adjoining the long-distance booth of the New York Telephone company. The company shows a general line of its goods, including Universal electric lamp holders, aluminum and steel lamp shades, and fire and water-tube boiler cleaners.

The Keystone Electrical Instrument company of



PLAN OF AMPHITHEATRE AND ARENA CIRCLES.

ELECTRICAL EXHIBITION IN NEW YORK.

McKinley and for the flag, and wildly waving the colors. The speech was enlivened with characteristic humor, and the orator's patriotic eloquence stirred the popular heart deeply.

A large number of prominent people were present, among them being W. Seward Webb, H. McK. Twombley, Henry B. Hyde, John E. Searles, J. W. Alexander, John Jacob Astor, General Louis Fitzgerald, Charles R. Flint, John D. Rockefeller, William Rockefeller, the Rev. Dr. Morgan Dix, ex-Senator J. Sloat Fassett, General Benjamin F. Tracy, the Rev. Dr. Lyman Abbott, President S. R. Callaway of the New York Central and Hudson River railroad, the Rev. Dr. Rainsford, Thomas A. Edison and Prof. F. B. Crocker.

The exhibition has many interesting features and is to last during the month. The officers and members of the New York Electrical society have devoted much thought and labor to its success.

The floor and gallery plans, with the names of the exhibitors, are shown by the accompanying cuts.

Notes of Exhibits.

A. D. French & Co. of New York make a showing of octagonal wooden poles, plain and treated, for electric-light and power use. This display is under the direction of Wood, Shaw & Co.

Wood, Shaw & Co. exhibit the Imperial lead and paper dynamo brushes manufactured under the supervision of H. M. Shaw, who is one of the pioneers in the dynamo brush business.

The Partridge Carbon company of Sandusky, O., exhibit, under the supervision of Wood, Shaw & Co. the various kinds of self-lubricating carbon and Philadelphia has a complete exhibition of both its switchboard and portable instruments. It is its purpose to erect a slate switchboard on which it will mount a full set of the various switchboard type of Keystone instruments suitable for central stations, railway power houses and isolated plants. The company also shows a full line of its new ground detectors and instruments specially designed for series arc-light service. Portable testing instruments are also displayed. A number of the new Keystone type "R" instruments, mounted on a panel board, are shown in practical service on a working generator circuit. This exhibit is under the charge of Elmer P. Morris of New York, but President J. E. Stevens will spend a considerable length of time during the month of May at the Keystone headquarters.

H. B. Coho, as agent for the Warren Electric Manufacturing company of Sandusky, O., has on exhibition an improved Warren alternator of 75 kilowatts capacity and intends to operate it with an 8-pole direct-current motor. This alternator is connected for double voltage. Half the capacity of the machine will deliver current, without the use of transformers, direct to 110-volt lamps; the other half will be connected up to a potential of 1,000 volts on current to be reduced by transformers. The machine will be excited by a late improved Warren direct-current dynamo, which is a bipolar machine, over-magnet type, and is of an entirely new design, combining many elements of extreme simplicity with exceptionally high efficiency. The alternator will be operated at a speed of 800 revolutions per minute, contains no brushes, collector rings or revolving armature, the current being taken from a stationary element of the machine.

The Bullock Electric Manufacturing company of Cincinnati had to give up its idea of exhibiting its motors on various machine tools. Both the Niles Tool Works and the American Tool Works company, upon whose tools the Bullock motors were to be placed, and the Bullock company itself, have been so rushed with orders that were imperative, that they could not give the necessary time to these exhibit machines, and machines built on these orders have been turned over for immediate delivery. The exhibit now consists of one 25-kilowatt engine-type generator, one 25-kilowatt belted generator, one 10 horse power type "N" enclosed motor and one type "T" controller. The controller is from a recent design, and the 10 horse power enclosed motor is of absolutely new design, being the first turned out on this pattern. It is entirely enclosed, being dust and waterproof, and is designed for use in foundries, on cranes, pumps, etc.

The Montauk Multiphase Cable company of New York displays its new automatic thermostatic interior electric cable in a booth located in the northeastern section of the garden, at the junction of the outer aisle parallel with Twenty-seventh street and the outer aisle parallel with Fourth avenue, some of its neighbors being the Electric Storage Battery company, the Sprague Electric company and the Peckham company. The purpose is to make the same exhibit as in the office at 100 Broadway. The company has recently placed upon the market a new and revolutionary line of electrical goods—in other words, thermostatic electric cables to be used for all electrical interior work, such as electric bells, electric gas lighting, electric fire and burglar-alarm, telephone and telegraph work, and even for electric lighting. In this system every wire installed, and used for whatever purpose, may have the property of discovering dangerous heat or flame in its vicinity, notifying the existence of the excessive heat at any and all points desired, both locally and at the central station. The company makes an exhibit of both local and central-station work, the latter in connection with the telephone district service boxes, thermostatic devices, auxiliary fire alarm boxes and all other electrical transmitting devices. The Montauk Multiphase Cable company manufactures the only automatic thermostatic electric cable in the world, and it is its purpose to bring out all its salient points in connection with every interior device now used by the public.

In a recent article on foreign trade in Russia, showing German enterprise and the possibilities for Americans, it is stated that the "technical bureaus" of the large German manufacturing firms keep a stock of every type of machinery, which is constantly renewed according to sales effected. Take, for instance, the bureau of the Allgemeine Elektricitäts Gesellschaft, Berlin, which is conducted by the engineer, Mr. Seiherbatd. Everything this large concern, whose capital is $25,000,000, produces at home may be found there. This bureau has been established for account of the company, which allows the manager a commission of 10 per cent and pays all expenses of the bureau.

General Electric Company's Annual Report.

The annual meeting of the General Electric company will be held at Schenectady, N. Y., May 10th, at which time 13 directors will be elected for the ensuing year, the annual reports of the president and several vice-presidents will be received and the condition of the business explained.

President Coffin's report is a general review of the year's business, the details of which are considered in the department statements. The president's report is appended:

The past year witnessed a revival in business, which increased rapidly in activity and volume during its latter months.

In the last annual report attention was called to the fact that your company began the year with less orders on hand than previous seasons. As a result of this, the actual output of your works has been slightly smaller than in previous years, although the orders received during the period have shown a marked increase. This increase will be reflected in the shipments of the ensuing year.

A careful scrutiny of the assets of your company, other than its patents, leads to the belief that previous values were conservatively fixed, and no changes of any significance have been necessary.

The patent account of the company has been kept at substantially the same amount on its books since the organization of the company. The question of a revaluation of patents is one to which consideration should be given at the proper time.

BUSINESS OF THE YEAR.

Gross earnings		$19,594,938.07
Less expenses	10,737,692.02	
		$1,797,216.05
Interest and discount, and interest and dividends received on securities owned	389,789.16	
Less interest on debentures	333,333.35	
		56,455.81
		1,853,701.86

It has been the practice of the company to write off the amounts expended for additional factory facilities. It is thought that these allowances are not more than are required to properly provide for depreciation in all your factory plants taken as a whole.

At the annual meeting of the stockholders held four years ago the question of reducing the company's share capital in the manner prescribed by law was referred to the directors. Since that time the matter has had the earnest attention of your board, and it is their hope that a plan will be submitted for your consideration at an early date, designed to provide for a suitable reduction of the share capital of the company, with a view to the resumption of dividends.

THE PATENT SITUATION.

The patent situation has not materially changed since the last report to the stockholders. The company has secured many important patents during the year, by inventions of its engineers and experts and by purchase.

One of the Van Depoele trolley patents which had been uniformly sustained by the courts up to last summer has been adversely passed upon by the Court of Appeals for the Second Circuit. This decision was on a motion for preliminary injunction and is not final. The invention was an important contribution to the electric railway art, and no court has questioned its great merit. There is reason to believe that the technical objections to the claims of the patent, upon which was based the decision of the Appellate Court overruling that of the Circuit Court in favor of the patent, will be found upon full consideration at final hearing to be insufficient to defeat the patent.

In view of the fact that nearly all of the railway companies in the country that would be likely to use the overhead trolley system are now electrically equipped, and that the third rail and underground conduit methods are being rapidly adopted for the important new enterprises, an adverse decision in this case will have but slight effect upon the business of your company.

Many other cases based upon patented inventions of great value, including a number on the overhead trolley system, are being pressed against infringers, in which early and, it is believed, favorable decisions are expected.

DEPARTMENTS OF SALES, MANUFACTURING AND FINANCE.

Your careful attention is called to the reports of the vice-presidents having these departments in charge.

Your directors desire to express their appreciation of the valuable service of your admirable engineering and commercial staff, as a result of whose ingenuity and vigilance the company has more than maintained its position of pre-eminence in the varied and constantly increasing applications of electricity.

First Vice-President Griffin's report of the sales department shows that the orders received during the year largely exceeded those of the previous year and made it necessary for the company to enter upon the present year with a large number of unfilled orders than ever before in its history. The report contains considerable data that cannot fail to prove interesting. A condensed report of the operations of the year is presented:

Total sales (amounts billed to customers)	$[illegible]
Cost of goods sold, general expenses and taxes, including sundry losses and allowances for [illegible]	[illegible]
Profit on sales	$[illegible]

From this fund should be deducted [illegible] interest, etc., as shown in the report of the second vice-president.

LIGHTING DEPARTMENT.

We have received during the past year orders for [illegible] kilowatt capacity of our lighting generators and [illegible] machines, as against orders for the year [illegible] of [illegible] kilowatt capacity, an increase of [illegible] per cent.

RAILWAY DEPARTMENT.

Orders received (money value) for railway apparatus has shown an increase of [illegible] per cent. over 1896.

Orders for railway generators aggregated [illegible] kilowatts. The average size of the railway motor has increased to [illegible] horse power, while the average railway generator for the year was [illegible] horse power, as against [illegible] horse power in 1896.

POWER AND MINING DEPARTMENT.

The growth of business in the sale of electrical apparatus handled by this department is strikingly shown by the following comparison of orders received for the years named:

Orders for 1893 were 36 per cent. in excess of orders for 1892.
Orders for 1894 were 126 per cent. in excess of orders for 1893.
Orders for 1895 were 19 per cent. in excess of orders for 1894.
Orders for 1896 were 60 per cent. in excess of orders for 1895.
Orders for 1897 were 60 per cent. in excess of orders for 1896.
Orders for direct-current and induction motors aggregated 19,531 horse power, as against 15,171 horse power in 1896. Orders for multiphase generators aggregated 49,902 horse power, as against 25,697 horse power in 1896.

Total transmission lines installed in connection with General Electric apparatus, 336 miles, as against 232 miles in 1896.

SUPPLY DEPARTMENT.

The supply department has handled 111,239 separate orders during the year, or 23 for each working hour. The orders received in 1897 exceeded by 20 per cent. the orders received in 1896.

The supply stocks carried at our local offices have been decreased about 10 per cent. during the year, and of the present total 90 per cent. consists of active supplies, a great improvement over previous years.

The following are some of the principal articles handled by the supply department:

WATTMETERS.—Total number ordered during the year 36,872, an increase of 18 per cent. over 1896.

MEASURING INSTRUMENTS.—Total number ordered during the year 3,369, an increase of 38 per cent. over 1896.

TRANSFORMERS.—Total number ordered during the year 11,198, an increase of 38 per cent. over 1896.

ARC LAMPS.—Total number ordered during the year 24,158, an increase of 75 per cent. over 1896.

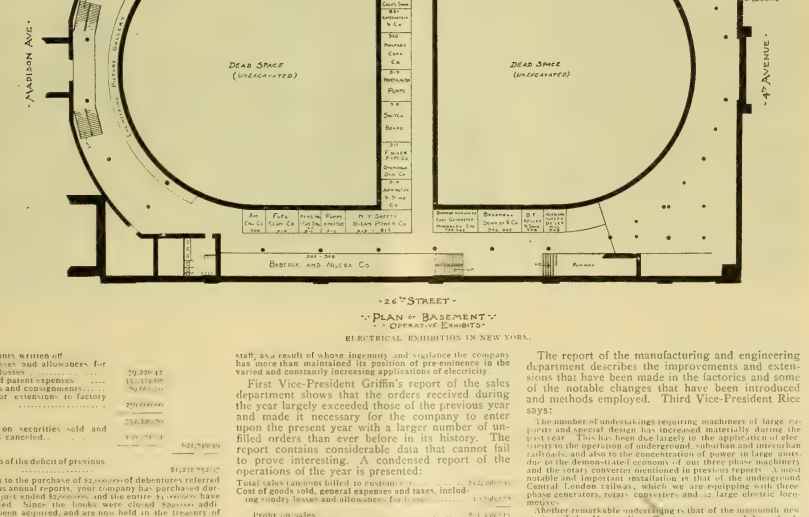
SOCKETS AND RECEPTACLES.—Total number ordered during the year 2,257,629, an increase of 36 per cent. over 1896.

FOREIGN DEPARTMENT.

The orders of the foreign department have shown a gratifying increase over the orders for 1896. Several notable contracts have been placed with us by our foreign companies—the equipment of the Central London underground railway and the equipment of the street railways in several European cities.

INCANDESCENT LAMP SALES.

The incandescent lamp orders for the year aggregated 6,857,239, of which 6,706,624 were shipped. This is an increase of about 10 per cent. over the year 1896.



ELECTRICAL EXHIBITION IN NEW YORK.

Deduct amounts written off		
Sundry losses and allowances for possible losses	79,220.42	
Patents and patent expenses	[illegible]	
Inventories and consignments	[illegible]	
Reserve for extension to factory plants	[illegible]	
	[illegible]	
Less profit on securities sold and debentures canceled	[illegible]	
		[illegible]
Reduction of the deficit of previous years		$[illegible]

In addition to the purchase of $2,000,000 of debentures referred to in previous annual reports, your company has purchased during the year just ended $250,000, and the entire $3,000,000 have been destroyed. Since the books were closed $500,000 additional have been acquired, and are now held in the treasury of the company.

An increase is shown in the amount received from interest and dividends from securities owned. It is expected that the income from this source will still further increase from year to year, unless considerable sales of such securities should be made by the company.

The growth of your business has made it necessary to make further expenditures for additions and changes at your factories and in acquiring much additional machinery.

Plans have been prepared and contracts partially closed for a new foundry and a large and important machine shop, the large building referred to by your company.

In anticipation of the investment in the construction and equipment of these new shops, which it is recommended will cost about three-fourths of $2,000,000, has been deducted from the profits of the past year and carried to factory reserve account.

[illegible] on $[illegible] for four months and on $[illegible] for eight months.

The report of the manufacturing and engineering department describes the improvements and extensions that have been made in the factories and some of the notable changes that have been introduced and methods employed. Third Vice-President Rice says:

The number of undertakings requiring machinery of large capacity and special design has increased materially during the past year. This has been due largely to the application of electricity to the operation of underground, suburban and interurban railroads, and also to the concentration of power in large units, due to the demonstrated economy of our three phase machinery and the rotary converter mentioned in previous reports. A most notable and important installation is that of the underground Central London railways, which we are equipping with three phase generators, rotary converters and 24 large electric locomotives.

Another remarkable undertaking is that of the mammoth new station of the Metropolitan Traction company of New York. From this station enormous electric generators will operate, through the medium of rotary-converters and other machinery of our design and manufacture, the electric street cars through out nearly the entire borough of Manhattan.

In no last report I called attention to the value of our rotary converter, a species of rectifying link between the alternating and continuous current systems which enables existing continuous-current plants to add the advantages of alternating current generation and economical transmission to the simplicity and effectiveness of the continuous current distributor. The economies which then result from the substitution of a single large alternating-current power station for a number of small stations is well illustrated in a notable installation of such apparatus made during the past year by the Edison Illuminating company using our three phase generators, rotary converters, synchronous motors and other appliances.

The number of long distance transmission plants has greatly increased during the past year, so that we have now [illegible] operating especially in such plants [illegible] over 10,000 horse power, and

among these some 20 installations are operating at potentials of over 10,000 volts and transmitting a total of some 50,000 horse power to distances varying from 10 to 40 miles. The 5,000 horse power plant at Ogden, Utah, has been in operation for nearly a year, transmitting power to Salt Lake City, a distance of 36½ miles, at a potential of 16,000 volts. We have now under construction apparatus intended for the transmission of over 4,000 horse power from a distant water power 80 miles to the city of Los Angeles, Cal., at a pressure of 33,000 volts. The St. Anthony Falls plant, mentioned in my last report, has been completed and is now in regular operation, furnishing power to the street railways of Minneapolis and St. Paul, Minn.

In the city of New Orleans, La., we shall soon have in operation a novel plant of some 4,000 horse power, which will be used to operate pumps for the drainage of the city. Three-phase machinery will be employed.

The driving of all machinery in cotton mills and factories by electric motors is increasing rapidly, even where the original source of power is a steam engine located in or near the mill or factory itself.

The United States Navy is adopting the electric drive in place of steam or hydraulic machinery for ventilating, pumping and hoisting on shipboard and for lowering and elevating guns and for turning turrets on the warships. This is in addition to the recognized use of electricity for lighting and small power work.

We shall soon be operating our Schenectady works from a distant water power. We have contracted for a supply of 2,000 horse power from the falls of the Hudson river at Mechanicsville, 19 miles from Schenectady. A novel feature of this transmission is that the generators, each of 1,000 horse power, have been constructed by us to produce directly a pressure of 12,000 volts, thus saving the cost of the usual intermediate step-up transformers.

Second Vice-president Ord's report contains the balance sheet and statement of profit and loss, which include the assets and liabilities and profit and loss accounts of the Edison General Electric, Edison Electric Light and Thomson-Houston Electric companies (which, for convenience of bookkeeping, are consolidated with those of the General Electric company) at January 31, 1898. Following is an abstract of the report:

Patents and Franchises.

During the year there was expended for acquiring new patents and in patent litigation $333,334.68, all of which has been written off to profit and loss, leaving the patents, franchises, good will, etc., of the company standing unchanged at $8,000,000.

Factory Plants.

A summary of the changes in this account since the last annual report is as follows:

	Book Value Jan. 31, 1897.	Cost of Additions.	Written off for Depreciation.	Book Value Jan. 31, '98.
Real estate....	$1,795,000.00	$164,715.35	$102,670.70	$1,857,044.65
Machinery......	1,605,000.00	183,879.85	245,924.50	1,542,955.35
Patterns........	1.00	71,450.87	71,450.87	1 00
Sundries........	1.00	18,874.06	18,874.06	1.00
Totals.......	$3,400,002.00	$438,920.13	$438,920.13	$3,400,002.00

	Jan. 31, 1897.	Jan. 31, 1898.
Book value of Schenectady plant......	$2,157,000.90	$2,300,000.90
Book value of Lynn plant	993,000.80	900,000.80
Book value of Harrison plant.........	250,000.30	200,000.30
Totals	$3,400,002.00	$3,400,002,00

Summary of Stocks and Bonds.

	Par Value.	Book Value.
Stocks enumerated in Schedule A....	$ 8,311,331.67	$3,772,389.10
Bonds enumerated in Schedule A....	5,165,455.28	3,423,082.32
	$13,476,786.95	$7,195,471.42

Grinding Wheels for Street-railway Service.

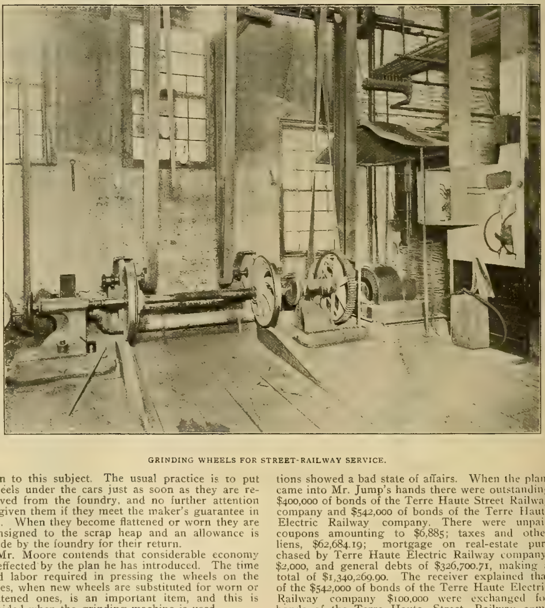
There is considerable difference of opinion between street-railway men and makers of car wheels as to the economy of grinding car wheels, so much so indeed that it seems as if each particular case would have to be decided for itself.

During the last few years the Chicago City Railway company has collected considerable data on the South Side system, and the conclusion reached by the master mechanic, E. C. Moore, is that the life of a car-wheel is increased and the efficiency of the service is promoted by grinding wheels before they are put under the cars as well as after they have become worn. Last year the company used 3,143 wheels, and the average term of service was 14 months. All of these wheels when received were pressed upon axles, sent to the grinding room and then put under trucks as required. They are continued in service until they become worn or flattened and then returned to the shop, where they are put through the grinding process and once more put under the cars. In particularly trying service this operation may be repeated several times in the course of a year with one pair of wheels, but in many cases little attention is required after the wheels are first put under the car after having been polished up on the grinding stone. Mr. Moore claims that the wheels run much more smoothly after the grinding process.

Probably a majority of the street-railway companies of the country have never given any attention to this subject. The usual practice is to put wheels under the cars just as soon as they are received from the foundry, and no further attention is given them if they meet the maker's guarantee in life. When they become flattened or worn they are consigned to the scrap heap and an allowance is made by the foundry for their return.

Mr. Moore contends that considerable economy is effected by the plan he has introduced. The time and labor required in pressing the wheels on the axles, when new wheels are substituted for worn or flattened ones, is an important item, and this is avoided when the grinding machine is used.

The accompanying picture gives an excellent idea of the arrangement, as it shows a pair of wheels undergoing the process. The grinder was made by the Plamondon company, and its capacity is said to be one set of wheels per hour. The grinder is driven by a 15 horse power motor wound for 500 volts and making 875 revolutions per minute. The motor was made by the Card Electric company of Mansfield, Ohio.



GRINDING WHEELS FOR STREET-RAILWAY SERVICE.

National Electric Light Association.

President Insull of the National Electric Light association returned to Chicago on Wednesday from New York, where he attended the opening exercises at the electrical exhibition. He says that the eastern delegation to the convention will be large and thoroughly representative. Much interest is already shown in the plans.

Among the special features for which arrangements have already been made is a discussion of the subject of "Municipal Ownership," which will be opened by Alex Dow of Detroit. The question of distribution methods will be handled by Herbert A. Wagner of St. Louis and Louis A. Ferguson of Chicago. The consideration of methods of charging will probably be one of the most interesting features of the meeting. The arrangements for this discussion have not yet been completed.

President Insull announces that a meeting of local representatives of the electrical interests will be called at once to arrange the details of the convention.

Affairs of the Terre Haute Electric Railway Company.

A meeting of the creditors of the Terre Haute (Ind.) Electric Railway company, which has been in the hands of Receiver Joshua Jump since the middle of last October, was held at the Terre Haute House on Tuesday of last week. The creditors represented included several banks and other bondholders and a number of concerns to which the Terre Haute company is indebted. Among the latter are the Terre Haute Car Manufacturing company, the Commercial Electric Supply company, the Diamond Electric company, John A. Roebling's Sons company, Illinois Steel company, Western Electric company, Stanley Electric Manufacturing company, Sunbeam Incandescent Lamp company, American Electric Heating corporation and the Hunter Fan and Motor company. The chairman selected was E. O. Brown of the First National Bank of Chicago, and J. B. Wallace of the Chicago office of the Stanley company was made secretary of the meeting.

The receiver's statement and his answers to questions showed a bad state of affairs. When the plant came into Mr. Jump's hands there were outstanding $400,000 of bonds of the Terre Haute Street Railway company and $542,000 of bonds of the Terre Haute Electric Railway company. There were unpaid coupons amounting to $6,885; taxes and other liens, $62,684.19; mortgage on real-estate purchased by Terre Haute Electric Railway company, $2,000, and general debts of $326,700.71, making a total of $1,340,269.90. The receiver explained that of the $542,000 of bonds of the Terre Haute Electric Railway company $100,000 were exchanged for bonds of the Terre Haute Street Railway company, $190,000 had been sold and $252,000 were held as collateral security, he understood, for $160,000 of debts. In response to inquiries the receiver stated that the books of the company did not show what the $190,000 of bonds sold for, who they were sold to, or what disposition had been made of the proceeds. The books, he said, did not show what part of the $252,000 of bonds used by the late management as collateral security was so used for merchandise account, and what part had been used for collateral for notes, or what notes had been issued, what the proceeds of notes were, what commissions or interest had been paid upon notes, or what disposition had been made of the proceeds of the notes. The company maintained a New York office, apparently in charge of Mr. Hoyt, through which the bonds and notes were marketed. The receiver found that all the assets of the company in New York when he took charge was a bank balance of $48.74. His statement does not show any cash assets in Terre Haute. From October 18, 1897, to April 1, 1898, Mr. Jump received $63,445.31 and disbursed $63,325.52. The receiver also reported that the condition of the

boilers, when the property came into his hands, was such that the plant practically collapsed, and under order of the court he issued $25,000 of receiver's certificates for putting in the boilers. In this special fund there was a balance sufficient to complete the erection of the new boilers.

In general the receiver had found things in a bad way—wages were in arrears; current taxes were past due; the plant had depreciated and business had been lost through inefficiency; holders of the real-estate mortgage threatened foreclosure unless the interest was paid; supplies had been conditionally purchased and would be removed unless the balance of the purchase money was paid, and so on. As a result of ambitious financing the affairs of the company appear to be badly involved.

After the situation had been discussed by the creditors, a committee was appointed to thoroughly acquaint itself with the company's affairs and devise a plan of reorganization or adjustment. This committee consists of Mr. Brown, Mr. Deming and Mr. Hussey, representing the banks; Mr. Carpenter and Mr. Wallace of the Western Electric and Stanley companies respectively, and Messrs. Kidder and Singer of the Illinois Steel company. An officer of the city government of Terre Haute will be a member of the committee ex-officio. This committee is now in charge of the creditors' interests, and the meeting adjourned subject to its call.

Before adjournment, however, the attendance of Russell B. Harrison, the president of the Terre Haute Electric Railway company, was requested and obtained. Mr Harrison stated that he could not tell at what time or at what price the $150,000 bonds of the company were sold, or what they netted the company or what disposition had been made of the proceeds. He could not tell what notes had been issued with bond collateral, what money had been realized upon these notes, what commission had been paid, or what disposition had been made of the proceeds. He would be able to ascertain this, he said, from his correspondence with Mr. Hoyt, and by getting additional information from Mr Hoyt. He explained that he was just about to accompany the militia company to Indianapolis on call of the governor, and that it would be impossible for him to state when he could give this information. He could not explain the increase in the indebtedness, what it represented, or what had been realized from the sale of the company's notes and securities without looking the matter up. He said that as soon as possible he would take the matter up with the committee, but he could not fix a date when he would be able to do it. Mr Harrison stated that he had possession of the stock book and would surrender it to the receiver. All but a few shares had been issued to him and were held by Mr. Thomas, he said, as security for the carrying out of the agreements he had made with Messrs. Kidder, Rippetoe and Thomas when he purchased the Terre Haute Street Railway company. Mr. Harrison was in a hurry, and, apparently not being able to give any information, was excused.

Electrical Fires.

The last quarterly report of the electrical bureau of the National Board of Fire Underwriters contains several interesting accounts of fires due to electricity. William H. Merrill, Jr., electrician of the board, commenting on the reports, says: "Additional reports are received of losses aggregating $700,000, all of which are supposed to be due to electricity, and in many of the accounts apparently very good circumstantial evidence is given, but they are omitted from this report because in many of the cases the fires burned up all evidence of their origin and in others the presumption is made that because electric wires were found near the point where the fire started and no other possible cause was discovered 'the wires' in some manner not specified caused the fires. A large number of casualties resulting in deaths and more or less serious injuries to persons are reported, and accounts are received of several instances where the presence of trolley and other wires in the street seriously interfered with the work of firemen."

Three "characteristic burn-outs" are illustrated in the report and through the courtesy of Mr. Merrill are herewith reproduced, with the accompanying explanation:

Fig. 1 is a reproduction of a photograph from F. R. Whitney, superintendent of fire alarms at Lewiston, Maine, and in the official report is numbered 2,164, the explanation being as follows: "Cross between arc-light and telephone circuits caused the telephone line to ground where it entered the office of a large grist-mill. The wire laid on a cross timber over the office and the arc formed by the ground ignited the thick dust on the timber and spread the fire rapidly. The mill was burned to the ground. Loss, $20,000."

The photograph from which Fig. 2 was made was furnished by Mr. Whitney also, and the cause of the accident illustrated is explained in paragraph 2,167, as follows: "A guy wire to a telephone pole was fastened to a three-story brick building and touched an eave-trough and drain which extended nearly to the ground, also being in contact with the suspension wire of a telephone cable on the pole. Workmen half a mile away, while putting up a derrick, allowed a wire rope to fall across the telephone cable and a trolley wire. The trolley current found no ground until it reached this building. At this point an arc formed between the guy wire and the eave-trough which set fire to the surrounding wood work. Fire was soon discovered and extinguished with small loss."

In Fig. 3 burned-out fire-alarm boxes are shown. Charles F. Hopewell, superintendent of firm alarms at Cambridge, Mass., who furnished the photograph, reports the cause to have been a cross between the fire-alarm and trolley wires. This is fire number 2,259 in the report and is thus officially recorded: "Cross between fire-alarm and trolley wire allowed the heavy trolley current to enter fire-alarm boxes located on switchboard. The shunt of the door of the boxes was small and of insufficient capacity. The loss to boxes amounted to $900, besides crippling the service until after a severe storm."

ELECTRICAL FIRES.

American Institute of Electrical Engineers.

The 124th meeting of the Institute was held at New York, Wednesday evening, April 27th, when a paper on "An Economy Test of Central Stations" was presented by Prof. W. E. Goldsborough of Lafayette, Ind.; also a paper on "A Novel Form of Thermo-electric Battery," by C. J. Reed of Philadelphia, which was accompanied by experiments. The discussion was participated in by Messrs. Cox, E. P. Thompson, Mailloux, Reed, Wintringham, Steinmetz and W. M. Mordey of London.

At a meeting of the executive committee in the afternoon the following-named associate members were elected: Wyatt H. Allen, San Francisco, Cal.; William H. Fitchugh, Bay City, Mich.; John Breckenridge Fleming, Austin, Nev.; George J. Henry, Jr., New York.; N. S. Hopkins, Schenectady, N. Y.; Robert Lindsay, Cleveland, O.; Frederick A. Muschenheim, New York; Newton L. Schloss, New York; Clarence M. Tappan, Silverton, Colo.; Ernest Stiles Vinten, New Haven, Conn.

There promises to be some difficulty between the electric-lighting company and the city of Stevens Point, Wis. The plant was assessed under the old law instead of the law of 1897, which taxes the gross earnings. The tax has not been paid and the property was returned as delinquent. A certificate issued on the property will be illegal. On the other hand, the company is liable to a fine for not returning a sworn statement of gross earnings.

Western Electrician.

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office: 809 Postal Telegraph Bldg., New York.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electrical or any of its practical applications is cordially invited, and the cooperation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—the only general electrical paper published in the West—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

Illustrated Electrical Patent Record	279

The New York office of the Western Electrician has been removed to 809 Postal Telegraph building. The new location is admirably adapted to the business, and the facilities offered are superior in every way to those formerly enjoyed.

It will be of interest to manufacturers and users of electrical measuring instruments to know that on April 24th the English patent No. 6,770, granted to Dr. Hermann Aron in 1884 for "Improved Means for Measuring Electric Currents," expired. The London Electrician says that this patent covered the original form of the Aron meter, which is said to have been practically a modification of the historical "ergmeter" of Profs. Ayrton and Perry. The patent also claims the application of the same electro-magnetic-control principle to clocks "regulated by a vibrating spring." Since the date of the patent several improvements have been introduced in the instruments, the latest type being self-winding and automatically compensating for inaccuracy in the regulations of the clockwork itself.

More public interest has been aroused in the cable system of the world by the war with Spain than has ever before been manifested. Few people had any idea of the extent to which these enterprises had been developed. They had grown accustomed to reading reports of events in the East, the West, the North and the South, but they did not realize the efforts that were required to gather and transmit this intelligence, nor the part that the great telegraph companies played in it. Now, however, when cable communication with Havana and Manila is interrupted and the daily recital of events in these important centers must be discontinued temporarily at least, the reading public begins to understand how much the world depends upon the modern telegraph and what an important part it plays in the everyday affairs of the human family.

President Lang of the American Street Railway association is a practical street-railway manager and a man of affairs. He takes a common-sense view of the relations between quasi-public corporations and municipalities, and in an address delivered before the students at Purdue University, which is presented in detail on another page, Mr. Lang says: "I do not believe that municipal ownership of such properties is wise in any sense, nor that much will be done in this direction, especially not if private corporations keep pace with the best methods of service and offer reasonable rates. I am one who believes that the community will deal with these corporations fairly if the corporations will be equally fair with the community." There can be no doubt that corporations which give good service at reasonable rates will have nothing to fear from the politicians who are howling for municipal ownership in order to secure additional patronage. It is only when corporations do not deal fairly with the people and the municipality that the demand for city plants receive the support of others than professional politicians.

The Topeka, which was purchased for the United States at London on April 2d, arrived safely in New York on May 1st and was at once put in active service. It is announced that the new cruiser was secured in a hurried manner, and that the negotiations for her purchase were carried on over the telephone. After the bargain had been verbally concluded Lieut. Colwell, the naval attaché of the American embassy, left his office and went to the Thames Iron Works, where the ship was purchased, and took possession in the name of the United States. The new acquisition to the American navy was built in Germany in 1884, at the time of the Chilian-Peruvian war. She was a sister ship to the Lima of the Peruvian navy, and was named the Diogenes, but was never delivered to Peru. The Diogenes was reconstructed in 1896 at the Thames Iron Works in England. Her displacement is 1,800 tons. Her load water line length is 250 feet and her beam 35 feet. She was built for an armament of six 4.7-inch rapid-fire guns, 10 six-pounders and six three-pounders. The 4.7-inch guns will be mounted, two on the forecastle and one in each of four broadside sponsons. The Topeka is brig-rigged and has no military tops. She has the distinction of being the only vessel of the kind ever purchased by telephone.

Inventors, manufacturers and patent attorneys have been clamoring for improvements in the Patent Office for several years, and while the department has been more than self-sustaining it has never been given the consideration which it deserves. Now, however, it is in a fair way to reap some of the fruits of persistent agitation, as the Platt bill for revising and perfecting the classification of letters patent and printed publications in the Patent Office has passed the Senate and is now pending in the House, with an excellent chance of soon being enacted into a law. The bill carries with it an appropriation to provide for three additional principal examiners, two first-assistant examiners, two second-assistant examiners, six third-assistant examiners and five fourth-assistant examiners. With this increase in the working force, the records of the office, now greatly in arrears, can be brought up to date and kept reasonably close.

The telegraph and the telephone are recognized as invaluable agents of civilization, but the part they play in developing unsettled countries is not generally appreciated. The report of the British South Africa company calls attention to these facts, the circumstance being mentioned that the telegraph precedes the road-making and keeps the outlying districts in touch with the headquarters of the company. In the event of a rising of the natives, the wires may be cut and communication interrupted, but the interruption gives the signal that trouble has occurred in a certain district. The total mileage of public roads maintained by the company is 2,230, and extensions are being made along the telegraph routes. The company's telegraph system was increased by 126 miles in 1896 and by 200 miles in 1897. On September 30, 1897, 1,856 miles of line and 2,583 miles of wire had been erected. The total amount expended by the company on telegraph construction up to March 31, 1897, was £139,677, and the net profit for the financial year ended on that date, after deduction of cost of maintenance, was £13,391. The telephone service is being extended gradually. There are now 182 miles of telephone lines connecting the forts, and several exchanges are being fitted up. The work now in progress ensures a comprehensive telephone system for the district within a comparatively short time.

According to report in the German technical press the electric motors on the new German warship Aegir were only fairly successful in practice during the recent tests. The account at hand does not state the type of machines used, and no reason is given for the noise of the motors, which is a cause of complaint. It is said that this electrical plant is the first of its kind to be established on a large scale in the German navy. Electric motors are used to drive 10 ventilators, and 14 other motors serve for manipulating the guns and rudder, for the ammunition hoists and for other purposes. The convenience of the electric motor for power on shipboard is acknowledged, but it seems that the generating plant had been designed on the assumption that not all motors would be working simultaneously. For lowering the lifeboats and keeping the searchlights going at the same time, there was not sufficient current to be had. The noise of the electric motors within the turrets is said to have been very disagreeable, and for the steering machinery steam seemed preferable. To put the rudder through 35 degrees required 28.7 seconds, and the first five degrees demanded five seconds' time; this was deemed unsatisfactory. The electric steering plant, moreover, was reported to be heavier than the ordinary steering engines. Raising the anchors proved almost too great a strain on the electric motors. Pneumatic ammunition lifts also appear more practical, it is said. It should be stated that the compass was very carefully watched during these tests of the electrical installation and that no disturbances were observed.

On American war vessels the electrical apparatus has worked with a very encouraging degree of success, and, as reported in another place, the electric ammunition hoists and turret-turning gear on the New York was perfectly reliable and efficient during the brief test of service in the bombardment of the fortifications of Matanzas last week.

WAR OPINIONS.

In answer to inquiries addressed to representative electrical men by the Western Electrician, asking for opinions on the probable effect of the war on the electrical industries, the following responses have thus far been received. It is fair to say that these letters were written before the news of the great victory of Manila Bay was received and that the pessimistic ones do not reflect the views of the Western Electrician.

Elisha Gray, Highland Park, Ill.: I do not believe that the electrical or other interests will be seriously affected by the war. There may be a temporary depression for a month or two in some lines of business. There will be, immediately, 125,000 more men employed by the government. Their places will have to be filled, and fortunately there are men ready to fill these places. War will increase the demand for many things. Wages will be higher and more men will be employed. When everybody is employed at good wages, and when there is a good home and foreign demand for our products, both agricultural and manufactured, we cannot help having good times. Whenever the government is a large buyer, as it always is in time of war, money is always scattered and it gets into the hands of a class of people who spend it. This was true during the war of the Rebellion, as all who are now past middle life well remember. I do not believe there will be any shock in electrical industries. I should rather expect that they would be stimulated.

C. C. Warren, Warren Electric Manufacturing company, Sandusky, O.: In my opinion the effect on the electrical industries of the present regrettable but wholly unjustifiable war will be varied in character. Certain localities and specialties will be benefited, since there will be phenomenal demand for electrical devices and appliances called for by the development of modern warfare. Modernized war means the utilization of every known force which may best be employed to aid destruction—that which will cause the most unspeakable human torture and create the most frightful havoc—this being warranted by the theory that the more appalling war becomes, and the more destructive and horrible the result, the sooner it will be ended, and in the main will entail less human misery. Electricity in its various departments will become a tremendous factor in the present war in ways innumerable, and our government must surely call for an immense amount of appliances. Industries supplying the demands of the government will also utilize electricity to a great extent, and electrical industries in certain localities will reap benefits. The war will doubtless check the development of interior railway schemes, retard intended extensive lighting and electric power projects, and will cause capitalists (the class always first frightened) to hesitate about investing, they preferring to continue the hoarding process until the war is over, thereby delaying what promised to be an active period of electrical development. I believe the war will delay and disturb more than it will benefit. Enterprises requiring the assistance of the timid capital will suffer, and that requiring capitalistic aid is, in my opinion, of greater magnitude than government requirements; therefore I cannot believe that war will inure to the advantage of the electrical industries of this country, taken as a whole.

E. J. Nally, Postal Telegraph-cable company, Chicago: It is hard at this time to state what the probable effect of the war will be on the electrical industries of this country, that is, so far as the telegraph is concerned. The telegraph business is a barometer of general business, and while it may fall off in certain directions, it is likely to increase in others, according to the way in which one branch of trade may be killed and the other stimulated by war. For example, the Postal is doing a very heavy press or newspaper business at this time, and our brokerage business is good at all points. The demand for press reports from all parts of the country is unprecedented. Newspapers in small towns heretofore content to use "plate" or "patent inside" are calling for a daily report by wire. Newspaper "special" business is also very heavy. In fact, at the present writing, everything seems to have an upward tendency, and the telegraph business is always good when there is a rise in prices and correspondingly poor when there is a decline.

B. E. Sunny, General Electric company, Chicago: The effect of the war on the electrical business will depend altogether on the money market. For eight months the money market has been very easy, and money has been abundant at low rates. Anyone with good credit standing could have what he needed on proper security of course, for additions and improvements or for new enterprises, so that there has been a very marked movement in the business of the electrical companies since the fall—indeed, it has been larger than at any time since 1893. With the declaration of war, work on all new enterprises of magnitude—except where the money is in bank to complete them—will stop, for the reason that no careful banker or capitalist will go into anything involving the expenditure of cash in the face of a long war that may call for the money of the nation and its citizens to protect what we already have. The situation to-day means that the banks will soon cease loaning, except for the legitimate wants of their regular customers and at higher rates; that new enterprises will be put aside and improvements and additions postponed, with the result that we shall have a repetition of the business depression from which we recently thought that we had just escaped. Of course the war may be very short, as we all hope it will be, in which case the American people will furnish another example of the alacrity with which they can transfer their attention from one subject to another.

George A. McKinlock, Central Electric company, Chicago: I think the electrical industries, owing to their close association with our railways, will be affected indirectly more than directly. The first effects that are noticed are the large government orders, which have been placed with the wire and manufacturing companies, taxing their capacity to supply immediate requirements, and affording an opportunity for the various electrical devices, which have been looked upon largely of an experimental character, to test their value for war uses. Indirectly, if the war is to be protracted, which I do not regard as likely, and the Spaniards are able to get within gun-shot of our coasts and maintain any sort of a position there, we naturally will feel the influence of a menace of this character in a drawing-in of capital and the unsettling of markets and our commercial enterprises, and in the event of our being defeated in an important naval engagement business interests will feel a shock that will be disastrous. Happily we have little to fear of the outcome of any contest with the Spanish forces on the sea, and if it were not for the daily papers, we would, in my judgment, not be aware that war exists, in so far as our business is concerned.

A. O. Fox, Northern Electrical Manufacturing company, Madison, Wis.: It is in my belief that the war will be short and decisive. Should it terminate promptly and in our favor, as I think it will, the effect will be to advance American securities, popularize America and things American. If this assumption is correct the final result would probably be some thing of a stimulus to manufacturing and an appreciation in prices accordingly.

J. W. Lieb, Jr., Edison Electric Illuminating company of New York: Thus far the war has had no sensible effect on the business of this company, which is confined to the generation and distribution of current on Manhattan Island, but the experience of an exclusively local company would hardly form a proper basis on which to gauge the probable effect on the electrical industries of the country in general.

A. Stromberg, Stromberg-Carlson Telephone Manufacturing company, Chicago: While the war may slightly delay some of the larger proposed work, we do not anticipate it will materially change any of the plans contemplated in the independent telephone business. We rather believe it will have a tendency to more rapidly increase the work in and between the smaller towns. We are pleased to say that it has not affected our business adversely.

J. W. Marsh, Standard Underground Cable company, Pittsburg: I do not believe that the war will affect adversely any existing electrical industries, but it will probably check new enterprises for a little while, if not until the war is over. Judging by our own business, neither "rumors of war" nor the war itself have been able to cause a diminution of commercial orders, while naturally the government orders for our goods have been very large and are likely to continue for some months. I do not believe that export business will be much injured in view of the small percentage of goods exported in American bottoms.

H. M. Atkinson, Georgia Electric Light company, Atlanta, Ga.: To answer this question correctly merely means to forecast the history of the war, and I must confess my inability to do this. The war may drag along without anything decisive done on

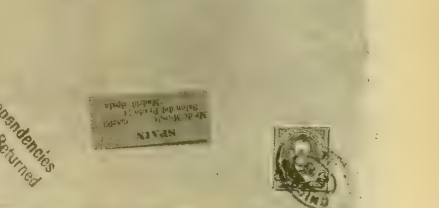
[Continued on page]

WAR NEWS.

No Mail Communication with Spain.—The postmaster-general has issued an order directing that all mail matter deposited in the postoffices of this country for transmission to Spain be returned to the senders or sent to the Dead-letter Office at Washington. This is, of course, a war measure, pure and simple, and something new to this generation of Americans. One result is to shut the Western Electrician, with other American periodicals, out of Spain. Readers of this journal will be interested in the photographic reproduction, slightly reduced, of a portion of the wrapper on a copy of last week's Western Electrician mailed to a Spanish subscriber in due course, but returned to this office by the postoffice authorities, with the reason plainly stamped thereon. Señor de Muralt will miss his paper, but doubtless he can obtain back numbers when the war is over.

Norman Harrington's Bravery.—Herbert W. Bowen, late United States consul-general at Barcelona, who is a passenger on the Cunard liner Etruria, now en route from Liverpool to New York, is credited with the following interesting story:

"During the morning of April 20th a mob of 3,000 or 4,000 people suddenly filled the square in front of the consulate, cheering for Spain and uttering other cries. I was breakfasting at the hotel on the opposite side of the square. This mob had come determined to get the consul, the eagle and shield. I managed to push my way through the people until I got my back to the consulate and faced the mob. There I awaited the result. I had hardly taken up my position when I noticed a man as big as myself (Mr. Bowen is about six feet high) pushing through the crowd. He came and stood beside me, did not speak, but faced the crowd, which continued to threaten us. Fortunately the mob had no leader, so, for a quarter of an hour, we two and the mob faced each other. Then the police and soldiers arrived and the mob melted away. I asked the stranger who he was and he replied: 'I am Norman Harrington of Chicago. This is my first day in Barcelona. It seemed to me as if there would be some trouble for the eagle up there, and I thought I'd take a bit of it.'"



NO MAIL COMMUNICATION WITH SPAIN.—WRAPPER OF RETURNED PAPER.

To electrical men an interesting feature of this story is the fact that Mr. Harrington is connected with electric-railway work. It is well known that the street-railway system of Barcelona is being equipped for electrical operation. The contractors are Dick, Kerr & Co. of London, but the sub-contract for the power-house generators and electrical station equipment was secured by the General Electric company of this country, while that for the engines went to another American concern, the E. P. Allis company of Milwaukee. Mr. Harrington, it seems, is one of the erecting engineers of the latter company. A Milwaukee dispatch to the Chicago Tribune states that he has been in the employment of the Allis company for about three years, but has been seldom in Milwaukee and but little is known of him by the company except that he is one of the most capable men in his line in the country. Mr. William W. Allis said that he could not recall Mr. Harrington, but supposed he had seen him at some time at the plant. He said: "I know that he has been in our employment about three years and is a well-educated and competent man. We have a contract with an English firm that is building electric railways in Trieste, Madrid, Barcelona and Valencia, and Mr. Harrington was sent to superintend the erection of all these plants. When the trouble with Spain broke out I remember there was a letter received from his mother, who was anxious about his safety. We immediately cabled the English firm to protect him, and we have received a reply to the effect that he will be fully protected. Although he is an American, he is working for an English firm and will not be molested. He will stay in Spain until the work is completed. I should judge from the dispatches that he is a good man outside of his

[Continued on page]

DEVELOPMENT OF THE TELEPHONE FIELD.

Telephone Equipment of the Stewart Building, Chicago.

The Stewart building, at the corner of Washington and State streets, Chicago, is considered to be one of the largest and finest office buildings in the West, and, as might be expected, it has a complete and convenient telephone system especially adapted for such buildings. Besides having in the building a large number of public telephones for use in connection with the city exchange, it has a private plant with a telephone in every office.

The private system was installed by the Stromberg-Carlson Telephone Manufacturing company of Chicago nearly a year ago, and was one of the company's first central-ringing and central-talking battery systems. In the office of W. A. Merigold, agent for the building, there are several desk telephones. These are the regular long-distance portable desk instruments, with a small push button in their base for calling central. Fig. 1 is the wall set used in the private system, consisting of the receiver, transmitter and switch of the regular type, mounted on a highly finished, solid mahogany backboard, with a push-button at the lower end and a round nickel-

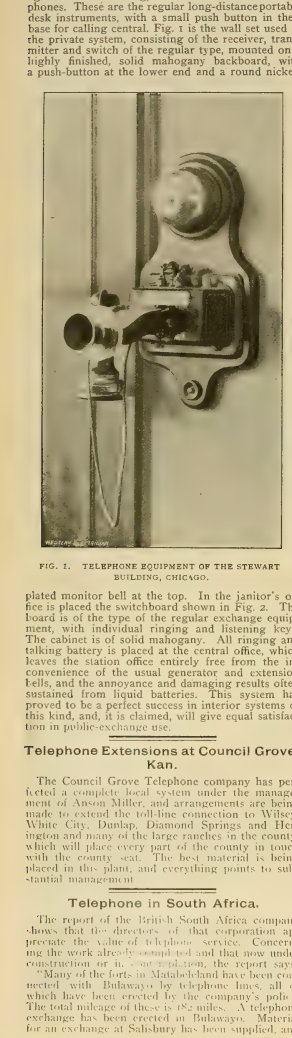


FIG. 1. TELEPHONE EQUIPMENT OF THE STEWART BUILDING, CHICAGO.

plated monitor bell at the top. In the janitor's office is placed the switchboard shown in Fig. 2. The board is of the type of the regular exchange equipment, with individual ringing and listening keys. The cabinet is of solid mahogany. All ringing and talking battery is placed at the central office, which leaves the station office entirely free from the inconvenience of the usual generator and extension bells, and the annoyance and damaging results often sustained from liquid batteries. This system has proved to be a perfect success in interior systems of this kind, and, it is claimed, will give equal satisfaction in public-exchange use.

Telephone Extensions at Council Grove, Kan.

The Council Grove Telephone company has perfected a complete local system under the management of Anson Miller, and arrangements are being made to extend the toll-line connection to Wilsey, White City, Dunlap, Diamond Springs and Herington and many of the large ranches in the county, which will place every part of the county in touch with the county seat. The best material is being placed in this plant, and everything points to substantial management.

Telephone in South Africa.

The report of the British South Africa company shows that the directors of that corporation appreciate the value of telephone service. Concerning the work already completed and that now under construction or in contemplation, the report says:

"Many of the forts in Matabeleland have been connected with Bulawayo by telephone lines, all of which have been erected by the company's police. The total mileage of these is 182 miles. A telephone exchange has been erected in Bulawayo. Material for an exchange at Salisbury has been supplied, and an order for material for an exchange at Umtali is being executed. The section of the African transcontinental line between Salisbury and Tete was destroyed during the native disturbances, and has been replaced by a section from Umtali to Tete, which follows a more healthy route, and is now completed. A portion of the old section has been restored as far as Mazoe. Considerable progress is being made with the line through the British Central Africa Protectorate toward Tanganyika, which has been completed to Kota Kota—a distance of 263 miles north of Blantyre and 595 miles north of Umtali—and is being rapidly pushed forward. The section already finished has been of the utmost service to the administration and to the imperial representatives in the British Central Africa Protectorate."

War Tax on Long-distance Telephone Business.

[Special correspondence of the Western Electrician.]

Washington, D. C., May 2.—The measure providing for war finances has been reported from the committee of the whole house with several amendments, among them the following:

"That any person, firm or corporation owning or operating what is commonly known as long-distance telephone line or lines, or other toll telephone lines, whether such line or lines, or any part thereof, is or are operated separately or in connection with the similar lines of any other person, firm or corporation, shall, on the first day of each month, return under oath to the collector of internal revenue in and for the district in which such person, firm or corporation resides, the number of messages transmitted over the respective connected or separate lines during the preceding month; the returns shall include the paid messages so transmitted from individual or other subscribers to the telephone service of the person, firm or corporation, and from the respective public pay stations of the person, firm or corporation, together with the amount received for each such message so transmitted. Upon the failure of any person, firm or corporation to make such returns, or for the making of false returns, it shall, upon conviction thereof, be fined not exceeding $500.

"On each message so transmitted, where the charge for which, according to such sworn returns, does not exceed 25 cents, the person, firm or corporation shall pay a tax of one cent; when the charge exceeds 25 cents and does not exceed $1.50, two cents; when the charge exceeds $1.50 and does not exceed $5, 10 cents.

"The taxes hereby imposed upon telephone messages shall be assessed by the commissioner of internal revenue, and the provisions of existing law relative to the assessment of taxes and of the 50 per centum penalty for neglect or failure to make returns and of the 100 per centum penalty for the making of false returns and of the collection of such taxes and assessed penalties are hereby made to apply to the taxes imposed by this section."

It is provided in this substitute bill that official government messages shall be exempted from all of these provisions.

Output of Bell Instruments.

[From the Boston correspondent of the Western Electrician.]

For the month ended April 20th the American Bell Telephone company put out the largest number of instruments in its history. The returns were heavy, however, so that the net output was a trifle more than one-half the gross output. The following is the record for the last month and also for the last nine months:

	1897-8	1896 7	1895-6.
Month April 20—			
Shipments	29,254	20,426	21,523
Returned	13,139	7,245	6,330
Net output	16,125	13,181	15,195
Since December 20—			
Shipments	109,921	73,735	76,518
Returned	51,697	28,156	28,462
Net output	58,224	45,579	48,056
Instruments in use	927,345	818,206	723,032

The Bell company has by close estimate 6,882 shareholders, holding an average of 38 shares and a fraction each. Theodore N. Vail has 4,784 shares in his name, and Lieut.-Governor W. Murray Crane 4,122 shares, these being the largest shareholders of record. The directors hold 4,304 shares between them, which is less than Mr. Vail's holding.

Telephones Cheap in Venezuela.

[From the New York World.]

The Merchants' association of this city held its last meeting of the present series of merchants' conventions recently. Charles R. Ruckland delivered an address, telling the great opportunities presented for the trade of the United States by the Venezuelan market. Said Mr. Ruckland in the course of his address:

"There are some things that Venezuela can teach the United States. One is how to run a telephone service profitably on a charge of $3.60 per month, with an additional tariff of only 10 cents for each long-distance message. And an excellent service it is too.

"The telephone is in every home in Caracas. Noticing the absence of ladies on the business streets, I was told they had no occasion to go shopping, as they sent their orders by telephone, and in the same way they ring up their friends to discuss the news of the day and society events."

Increasing Use of Telephone Service.

The New York correspondent of the Chicago Evening Post says: "If anything were needed to demonstrate further the value of the telephones—long and short-distance wires—it would be supplied by the use now being made of the system by the federal and state governments, as well as by the news-gathering organizations and the great newspapers in connection with war intelligence. To a large extent the telephone is taking precedence of the telegraph, and the revenues of the companies are increasing by leaps and bounds. But the companies themselves show no disposition to lower the charges for telephone service. Everywhere the attempt of the public to get a reduction by request or special legislation is stubbornly resisted."

The writer also calls attention to the fact that the recent meeting of the Bell Telephone company in Boston developed the fact that the output of telephones and the increase in the number of ex-

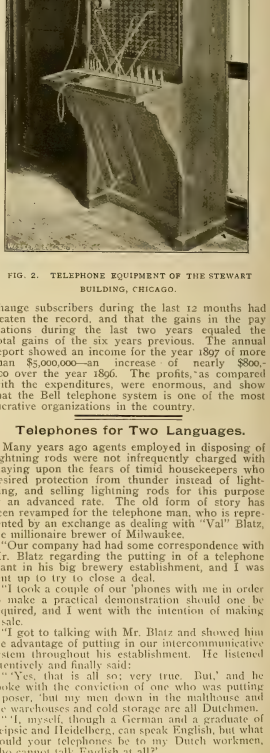

FIG. 2. TELEPHONE EQUIPMENT OF THE STEWART BUILDING, CHICAGO.

change subscribers during the last 12 months had beaten the record, and that the gains in the pay stations during the last two years equaled the total gains of the six years previous. The annual report showed an income for the year 1897 of more than $8,000,000—an increase of nearly $800,000 over the year 1896. The profits, as compared with the expenditures, were enormous, and show that the Bell telephone system is one of the most lucrative organizations in the country.

Telephones for Two Languages.

Many years ago agents employed in disposing of lightning rods were not infrequently charged with playing upon the fears of timid housekeepers who desired protection from thunder instead of lightning, and selling lightning rods for this purpose at an advanced rate. The old form of story has been revamped for the telephone man, who is represented by an exchange as dealing with "Val" Blatz, the millionaire brewer of Milwaukee.

"Our company had had some correspondence with Mr. Blatz regarding the putting in of a telephone plant in his big brewery establishment, and I was sent up to try to close a deal.

"I took a couple of our 'phones with me in order to make a practical demonstration should one be required, and I went with the intention of making a sale.

"I got to talking with Mr. Blatz and showed him the advantage of putting in our intercommunicative system throughout his establishment. He listened attentively and finally said:

"'Yes, that is all so; very true. But,' and he spoke with the conviction of one who was putting a poser, 'but my men down in the malthouse and the warehouses and cold storage are all Dutchmen.

"'I, myself, though a German and a graduate of Leipsic and Heidelberg, can speak English, but what would your telephones be to my Dutch workmen, who cannot talk English at all?'

"Well, I saw how the land lay. Old Val could not get it through his head that the telephone would transmit anything but the language of America. I was bound to make the deal, as I said before, so I remarked to Mr. Blatz:

"'I can put on some German receivers, if you so desire. I have some with me.'

"I connected up the 'phones, made a show of changing the receivers, and in half an hour Mr. Blatz was talking to one of his Dutchmen down in the malthouse. He was delighted.

"'You may put them in,' he said, 'and I shall want one German one in the malthouse, one German one in each warehouse, English ones in my office and the business office and a German one in the cold-storage house.'

"We closed the deal and Mr. Blatz was glad to pay $2 extra for each German enunciator we put in. When the 'phones were shipped from the factory I had them labeled German and English, re-

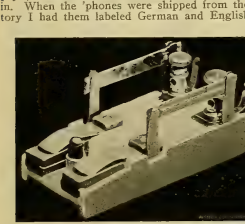

FIG. 1. CRIDER TELEPHONE SPECIALTIES.

spectively, and the big brewer was perfectly satisfied.

'It was five years before I saw Blatz again. He recognized me at once, and said with a hearty German laugh: 'You are the accommodating gentleman who put in the German and English telephones for me. Well, you are a good one.'"

Crider Telephone Specialties.

S. S. Crider of Sterling, Ill., has placed on the market the S. S. C. double-protective lightning arrester shown in the cut, Fig. 1. Experienced tele-

FIG. 2 CRIDER TELEPHONE SPECIALTIES.

phone men pronounce it an excellent device, highly efficient and well adapted to all classes of work. It is a spark and sneak-current protector. The telephone set shown in Fig. 2 is the S. S. C. portable counter and desk combination with no wall parts, save socket and plug like those used for electric-light connection. It is claimed that it will work over the same line and distance with Bell instruments and with equally good results.

The Telephone in the Orient.

English capital is developing the telephone business in the Orient, and, according to the financial statements of the companies engaged, is securing good returns on the investment.

The report of the directors of the Oriental Telephone and Electric company (limited) for the year ended December 31, 1897, which was presented at the annual meeting at London on April 27th, showed that the revenue account had a credit balance of £10,909 18s., including £629 14s. 3d. from 1896, and, after deduction of £2,858 8s., representing the interim dividend of 4d. per share paid on October 30th last, there remained £8,681 4s. 3d., which the directors recommend be appropriated as follows: £5,716 16s. in the payment of a final dividend of 8d. per share, free of income tax, making five per cent. for the year; £1,000 to extinquish balance debit of Colombo exchange "suspense account;" £1,000 to reserve, and £964 8s. 3d. forward.

The revenues of the Indian companies continue satisfactory. The Bombay company has paid a dividend of six per cent. against five per cent. for 1896, and has received from profits of the year a further sum of Rs.30,000, which has been decided desirable, in consequence of the continuance of the plague in that city and the unsatisfactory outlook in connection therewith.

The Telephone company of Egypt has declared the dividend on its six per cent. preferred shares, and its business still continues to develop.

The China and Japan Telephone company has paid its debenture interest, and is making fair progress both at Shanghai and Hongkong.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Western Electric Telephone company offers to extend its wires to Howard, S. D., if given sufficient inducement.

The telephone line between Springville and Whittier, Ia., is about completed.

The Iowa Telephone company has reduced toll rates from Columbus Junction, Ia., to Muscatine and Washington.

The Iowa Telephone company is cutting rates severely at Vinton, Ia., owing to efforts being made to establish a new company.

The local telephone company of Lake City, Minn., has just put in a new switchboard to enable it to handle 100 lines instead of 50, as heretofore.

Alline Brothers have accepted the management of the new telephone exchange at Fort Dodge, Ia. The company has over 200 instruments placed.

The Iowa Telephone company has established its office in new quarters in Independence, Ia., and will hereafter be open all night.

A local telephone exchange company is being formed at Benson, Minn.

The Northern Telephone company of Rush City, Minn., will extend a toll line to Minneapolis and St. Paul.

The Jefferson County Telephone company of Fairfield, Ia., voted to extend toll lines over the county to any place where sufficient encouragement should be offered.

Citizens of Red Oak, Ia., propose to establish a local telephone exchange.

The Iowa Telephone company is arranging to establish a telephone exchange in Dysart, Ia.

The Wisconsin Telephone company has now given Waupaca, Wis., an all-night service.

The Mississippi Valley Telephone company has deposited with the city clerk of Minneapolis a bond for $25,000 and an acceptance of the franchise recently granted.

The council of New Richmond, Wis., voted unanimously to request the application of the American Telephone and Telegraph company for long-distance connection. The council argued that it has county service over the independent lines and will soon have connection with Minneapolis and St. Paul over the same system. The council thought New Richmond had very little use for Chicago and New York connection. It also remembered in the days gone by the Bell company was implored to give the St. Croix valley telephone connection with the Twin Cities and would not give it. It is understood a similar application at Hudson, Wis., is likely to receive the same treatment.

Telephone systems are to be established at Rockwell City and Manson, Ia., at once.

The Union Telephone company of Richland Center, Wis., proposed a line between La Valle and Cazenovia. Late Saturday night it was learned that some farmers proposed a line along the same route. Twenty men were put to work on Sunday, and by Monday morning the 10 miles was completed, forestalling the farmers.

The Richland Center Telephone company will extend its lines to Reedsburg, Wis.

The Cedar Valley Telephone company is building a telephone line from Midland, Ia., to Traer, Ia.

The Wisconsin Telephone company will establish an exchange at Columbus, Wis., with 25 or more instruments.

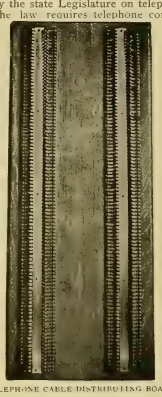
The Wisconsin Telephone company is preparing to build from Stevens Point, Wis., to Chippewa Falls, and north from Abbotsford, on the proposed line, to Ashland. It is expected to have these lines completed in about two months. The company recently proposed to establish an exchange at Marshfield. The council refused to allow it to enter Marshfield unless it would connect with the local exchange about to be put in. The Wisconsin company rejected this, but offered instead to take the local franchise and put in local and long-distance service. The council was willing to the company would work under its direction. This also was refused.

Telephone Cable Distributing Board.

F. Bissell & Co. of Toledo make the telephone cable distributing board shown in the cut. This board is suitable for use in an ordinary pole box or it can be placed on the wall of an exchange or elsewhere as may be desired. The cables are expected to enter from below or above, and the copper wires will spread to the inner rows of contacts on both sides. The connection is made by a screw provided with a washer. This joint should, of course, be soldered. All contracts are mounted on hard rubber backed by matched cast strips, braced. The whole is highly finished and is very handsome for station work. The fuse is also held by screw contacts, and the connection to the spider wire is made in the same manner as the cable wire and should also be soldered. The contacts are bent close to the ground strip, leaving a very short gap, which acts as a lightning arrester. The board can be used for a metallic circuit or a grounded or a common-return circuit. They are very compact. One with connection for a 200-wire cable takes a space only 16 by 40 inches. In this small space are connections for 200 cable wires, 200 spider wires and the fuses.

Telephone in Texas.

According to official returns the number of telephones in actual service in Texas is exceedingly small, taking into account the number of towns and the population of the state. A special telephone tax of 25 cents per annum for each instrument in use is imposed by the state Legislature on telephone companies. The law requires telephone companies to



TELEPHONE CABLE DISTRIBUTING BOARD

make a sworn statement to the comptroller as to the number of telephones in use. Following is a list of the companies and the number of instruments in operation at the close of the year, according to the comptroller's record:

Carter Kirwen Telephone company, Buffalo, three telephones.
Albany Telephone company, 18.
Abilene Telephone company, 127.
Bryan telephone exchange, 170.
Brownwood telephone exchange, 136.
Bosque Telephone company, 47.
Bosque County Telephone company, 5
Bonham Telephone company, 85.
Beaumont Telephone company, 80.
Buffalo and Centerville Telephone company, 3.
Calvert Telephone company, 42.
Corsicana Mutual Telephone company, 153.
Cuero Telephone company, 82.
Daly and Grapevine Telephone company, Tarrant county, 2.
Denton Telephone company, 61.
Eureka Telephone company, Gonzales, 10.
Gatesville Telephone company, 60.
Gonzales Telephone company, 72.
Hico Telephone company, 42.
Huntsville Telephone company, 72
Jewett, Centerville and Leona Telephone company, 7.
Leona, Deane's Store and Midway telephone line, 2.
Navasota Telephone and Construction company, 75.
Navasota Telephone company, 100.
Palestine Telephone company, 134
Round Mountain Telephone company, 7
Southwestern Telegraph and Telephone company, 8,604.

It will be seen from the foregoing list that the total number of instruments in use was 10,248, and consequently that the income from them amounted to $2,562. Judging from the increase already noted in the number of independent companies and the extension of their business, this sum will probably be doubled this year.

WAR NEWS.

[*Continued from page 269.*]

profession, but I really cannot tell anything about him."

Electrical Warship Machinery Successfully Tested in Action.—A significant paragraph of the Associated Press correspondent's report of the bombardment of the fortifications of Matanzas on April 27th is the following: "During the bombardment the New York's engines at intervals went slowly astern, keeping a steady range of 4,000 yards on Punta Gorda and 7,000 on Quintas da Recreo, the machinery working perfectly not only in the engine room but throughout the whole ship. This is especially true of the electric ammunition hoists and turret training gear, two of the most essential parts of a ship's equipment during action." This news is especially gratifying to those who have contended that the electrical transmission of power on shipboard is as reliable as it is convenient and economical. Of course the test is not actually conclusive, as the cruiser was not under the stress of an engagement with an antagonist of equal power, but it is still a valuable testimony to the efficiency of the motors during a time when the ship was using its gun batteries in earnest, with no especially prepared or favorable conditions for the electrical plant.

First Spaniard Captured.—Mr. John W. Ebert, who represents the Western Electric company in Mexico, scored the first victory over the enemy on April 20th, even before war was declared, as shown by the following extract taken from a newspaper, The Two Republics, published in Mexico: "Two gentlemen of this city recently paid a visit to the state of Guerrero on business connected with electric installation, Messrs. Ketchum and Ebert. On their return they stopped at Jojutla and put up at the hotel there. It happened that a Spaniard occupied one of two adjoining rooms, and the landlord, wishing to oblige the two Americans, by giving them these rooms, shifted the Spaniard to a down-stairs room. Messrs. Ketchum and Ebert went down to supper, and, on returning to their rooms, a revolver and belt, the property of Mr. Ebert, were missing. The landlord was at once notified and on inquiry found that the haughty Spaniard had been seen sneaking down stairs from above, where he had no business. The landlord charged him with the theft, which the Spaniard denied, and on the landlord insisting on searching his trunk, and the suspect refusing to permit same, a gendarme was called. The Spaniard again made objection and the jefe politico was called in to take a hand. He very soon settled the matter by locking the Spaniard up and keeping him in jail until he chooses to open his trunk for examination. There is no doubt that he stole the articles or he would not have hesitated to open and show up at first. So the first Spaniard has been captured by an American and held as prisoner. If every one of our boys does as well as Mr. Ebert the war will soon come to a close." Later advices direct from the seat of war state that the revolver and belt were found in the Spaniard's trunk and that he will spend six months in a Mexican prison.

Electricians in the Service.—Ensign J. B. Caboon, U. S. N., retired, has been ordered to report at the Brooklyn Navy Yard immediately for service. Mr. Cahoon is well known in the electrical business, having been prominently connected with the old Thomson-Houston company and other concerns.

General Greely, chief signal officer of the United States Army, has wired Capt. W. J. Lloyd that it is the expectation that a regiment of electricians will be raised for use in the existing war, but that no definite arrangements have been made. Captain Lloyd is the assistant district superintendent of the Western Union Telegraph company at Chicago.

The General Electric company has posted a notice at the works in Schenectady stating it to be "the intention and desire" of the company to re-employ all employes who may leave their work to enter the government service if the employes who thus display their patriotism are not "incapacitated for duty" after their terms of service.

Lieut. W. F. C. Hasson has been placed in charge of the electrical firing of the protective topedoes and mines in San Francisco harbor. Lieut Hasson is a well-known and experienced electrical man and was formerly a navy officer. He was chief of the electrical department of the California Midwinter Exposition.

Mr. Willard E. Case, vice-president of the New York Electrical society, has addressed a letter to Prof. F. B. Crocker of Columbia University in which he says: "In view of the fact that the efficiency of electrical fighting equipments on land and sea will form a vital factor in the present war, I would submit to you as the representative of the electrical department of Columbia University and as a member of the council of the American Institute of Electrical Engineers, the following suggestion: That the professional and skilled electricians of our universities, colleges and electrical societies shall form themselves into a body which shall supplement the electrical corps engaged in active work on the water and in the field, to be available to the government for expert advice in all matters relating to the utilization of electricity in naval and military operations, thus adding to the present regular expert electrical resources of the government."

Telegraphic Communication with the Philippine Islands.—The lack of a trans-Pacific cable under American control was keenly felt after the brilliant naval victory of Commodore Dewey and his fleet in Manila Bay on May 1st. The action was begun early on Sunday morning, but the news was not known in Chicago until eight o'clock in the evening, although the difference in time is ten hours in favor of this city. The Manila end of the route is, or was, under Spanish control, and so the news came by way of Madrid, although afterward some details were received through the British Foreign Office. At this writing (Thursday) no official report has been received from Commodore Dewey, but this delay is doubtless due to the exigencies of the military situation. Cable communication with Manila is controlled by the Eastern Extension Telegraph company, an English corporation. There is a single cable laid from Hongkong to the island of Luzon. This is the only means of telegraphic communication between the Philippine Islands and the rest of the world. The lines of the Eastern Extension company extend south from Hongkong and afford connections with the Indo-European and the Eastern Telegraph companies' systems. Northward from Hongkong the cables of the Great Northern company extend to Vladivostok on the coast of Siberia, which is the eastern terminus of the land lines connecting Northern Europe with the Orient. The original landing place of the Hongkong cable on the island of Luzon was at Cape Bolinao, about 90 miles north of Manila, a land line completing the connection, but the latter having been frequently cut by the insurgents, the company recently extended the line from Cape Bolinao to Manila by submarine cable. The ordinary commercial rate from Chicago to the Philippine Islands is $2.41 a word.

At this writing it is reported that the cable has been cut. A New York dispatch of May 2d gives Superintendent Smart of the Commercial Cable company as authority for the statement. He says: "This was not the work of insurgents. It may have been done by Commodore Dewey's orders, but my impression is that it was done by Spaniards near Bolinao, upon receipt of orders from Manila, which is in communication with Bolinao by a land and also by a sea line. If the submarine wire between Manila and Bolinao alone had been cut it would still be possible to communicate with Hongkong from Bolinao. The cable from Bolinao to Hongkong belongs to an English company, but the Spaniards would not hesitate to cut it, especially in view of their recent serious reverse." A London dispatch of May 3d says that tests from Hongkong show that the cable was cut 50 miles from Manila. A week or a fortnight may elapse before it can be repaired, it is said.

West Indian Cables Intact.—Contrary to a widespread impression and a direct statement in the daily newspapers, it does not appear that the United States government has as yet cut any submarine telegraphic cable. A late inquiry at the Chicago office of the Western Union Telegraph company by a representative of the Western Electrician elicited the information that no notice of the cutting of the Key West-Havana cable had been received. On the contrary the notice to employes not to accept code or cipher messages to go through Key West implied that the cable was in operation. The censorship of the messages sent over this cable is, however, rigidly maintained. Captain James Allen has gone to Key West to relieve Captain R. E. Thompson as censor of press dispatches. He is a native of Indiana, from which state he was appointed a cadet at West Point, in 1868. After his graduation from West Point, in 1872, he became successively second lieutenant, first lieutenant and captain in the Third Cavalry. In 1886 be became adjutant in the same regiment. His last place has been that of signal officer on Governor's Island.

At the New York office of the United States and Hayti Cable company, the following notice was posted on April 30th: "As the United States government has placed a censorship on code and cipher messages for places between Hayti and beyond, we are obliged to decline all messages except those written in plain language." Lieutenant Joseph E. Maxfield of the Signal Corps was installed as the government censor by General Greely.

All messages to Puerto Rico as well as to Spain and Cuba are subject to censorship. General Greely is reported to have said that at present there is no cable running from the United States that is not under proper restrictions as to the character of the messages sent. Gen. Greely has amicably adjusted these matters with the Western Union Telegraph company and with the Postal Telegraph-cable company. "Both of these companies," he says, "have patriotically accepted the restrictions placed upon them by the government, and no cipher messages are handled between this country and the West Indies over American cables except such as are exchanged between the officers of the United States and neutral ambassadors and ministers and the designated consular officers of the country they represent in the West Indies. While the government has nominally occupied those offices, yet the full telegraphic control remains in the hands of the officers of each company, and proper security is insured by swearing into the United States service the managers and assistants in the cable offices."

The Signal Service.—Capt. W. J. Lloyd, the chief signal office of the Illinois National Guard, has tendered the services of his corps to the government either individually or collectively, but as the Signal Corps of the regular army has been increased to 200 men, the services of the state signal troops will not be needed, for the present at least. Capt. Lloyd is a popular officer of the Western Union company in Chicago, and many of the men in his command are telegraphers. However, he has assisted the government by securing a portable gas generator for the captive balloon which is to be used in making observations along the Atlantic coast, as noticed in the Western Electrician of April 23d. This generator was made in Chicago and shipped to New York.

Until last October the Morse alphabet was used by the Illinois Signal Corps as a standard, but in order to make the work interchangeable with that of the Navy Department the Meyer code was later adopted. The members of the corps are all experts in the use of the heliograph, flag, torch and telegraph.

An elaborate signal-service system along the southern coast of Long Island, with 34 stations, will be manned by the New York naval militia. Should a patrol boat sight one of the enemy's ships approaching Long Island Sound or New York Bay she would immediately put in under full steam for the nearest life-saving station on the southern Lond Island coast and signal the militiamen stationed there of the approach of the invading ship. The news would be at once sent on by telephone to Fire Island, Quogue or Montauk Point, whichever station was nearest. These stations are in direct telegraphic connection with the navy yard at Brooklyn. So soon as the scout boat's message was received by telephone at one of the three signal stations named it would be immediately telegraphed to the navy yard.

It is said that for the first time in the experience of any army in actual service the commanding officers of the United States troops will have complete outfits for maintaining telephonic communication with the various brigades and regiments that go to make up divisions or corps of any army. For this the officials are indebted to General A. W. Greely, the chief signal officer. By means of the communication thus afforded commanders will be able to immediately send instructions to subordinates in the field and then receive reports of movements. General Greely also has equipped and ready for service his field telegraphic outfit.

Commodore Dewey Interested in Electric-light Signaling.—A report from Hongkong, brought by the steamer Gaelic, states that the night before the Gaelic left Hongkong (about April 8th) Commodore Dewey gave an exhibition of electric-light signaling. The commodore is particularly interested in this branch of naval tactics, as he was at the head of the naval commission which authorized and formulated the method and code. The passengers on the Gaelic describe the exhibition they saw as interesting. The signals were answered almost instantaneously from the other ships anchored at various distances and in various directions.

Wiring Along tho Coast.—Official notice has been given to navigators that submarine mines have been placed in New York and other harbors along the Atlantic and Gulf coast. The regulations allow no vessels to pass the entrances to the harbors between sunset and sunrise and give other rules for the safe navigation of friendly vessels. Patrol boats enforce the orders of the authorities, and a guard boat, the Surprise, is used to protect the mines and cables in the Narrows and New York Bay from the knives and nets of shad fishermen.

A dispatch from New Haven states that the Southern New England Telephone company has begun laying a set of private wires for the United States government along the shore of Connecticut, from Goshen Point, near New London, to connect that place with the main line. Other shore stations to be connected with the main circuit are Race Point, Sachem's Head, Sheffield Island, Noroton Point and Lighthouse Point. A cable will be laid across Long Island Sound to Sheffield Island. Two trunk wires have just connected the forts at the eastern entrance of the sound with New York and Washington. Major S. S. Leach has just purchased 65 miles of cable for the submarine mines to be submerged at New London, Fisher's Island, New Haven and Bridgeport harbors and at the mouth of the Connecticut River.

The plant of the American Electrical Works of Providence is running overtime getting out wire cables for the United States government. It is understood that the cables are to be used with submarine mines.

Miscellaneous Notes.—Key West is a frontier town in the present war, but the inhabitants accept the situation very quietly and take their afternoon siestas as usual. Business is undisturbed, and the Key West Street Car company is leisurely supplanting its horse-cars by an electric system, undismayed by the presence of soldiers and war vessels.

Electric fans are pressed into service in a Chicago department store to furnish the breeze to blow out American flags that are used indoors and which would otherwise hang limp and still.

There is a telegraph operator on duty at the White House day and night, and the president re-

ceives not only official and private messages, but has all of the Associated Press reports.

The Sprague Electric company, at its works in New York City, is running day and night upon contracts for interior conduit and power motors for the government. The interior conduit manufactured by the Sprague company is the standard of the United States government, and it is used upon a number of warships and cruisers.

Gardner C. Sims, the wealthy engine builder of Providence, has, it is said, volunteered for service as an engineer in the navy. He passed his examination, has been accepted and will serve on one of the auxiliary cruisers as chief engineer without pay. Other men of prominence have offered their services for engineering work. L. B. Perkins of Hartford, Conn., a designer of steamship engines, has volunteered, and will be commissioned chief engineer in the navy. Prof. W. S. Aldrich, professor of engineering in the University of West Virginia, has also volunteered and is now awaiting examination. Prof. M. E. Cooley of Ann Arbor, son of the late Judge Cooley, will receive his commission, and Prof. H. W. Spangler, head of the department of steam engineering in the University of Virginia, is to be examined.

On April 29th the three warships at Hampton Roads gave a brilliant exhibition of their searchlights. The vessels were the Texas, the Massachusetts and Texas two each. They flashed the lights on every ship at anchor in the roads. One of the armed steam launches doing picket duty three miles away started to sneak up on the fleet. The operators of the lights on the Brooklyn caught the launch when it was about two-thirds of a mile away and the next instant the lights from the Texas and Massachusetts were trained upon the approaching craft.

Governor Black of New York has received a letter stating that the Western Union Telegraph company will transmit at "government rate"—that is to say, at the regular United States government rate—the messages concerning the enlistment and movement of volunteers or state militia during the war with Spain.

WAR OPINIONS.

[*Continued from page 269.*]

either side, in which event business of all kinds will remain in a waiting attitude. If our government should push the war aggressively, successfully and quickly, I believe all business would feel a new impulse. There can, of course, be but one ultimate result of the war, though whether this will come in a few months or will be long deferred is the difficult question to answer. The fact that war will do no one permanent good, in my opinion, is not open to argument. Now that we are in it, it should be pushed with all the aggression, rapidity and strength that the country is capable of.

J. J. Nate, Standard Telephone and Electric company, Madison, Wis.: An opinion at this time as to the probable effect of war on the electrical industries of the country seems premature. It is, of course, quite apparent to everyone that in certain lines the industry must be benefited, as electricity enters so largely into modern warfare, and it is equally apparent that there are other branches of the business which must suffer. I may say these conditions are also applicable to other lines of manufacture. Many of our large transportation companies predict disastrous results should the war be of long duration. As a loyal American citizen, filled with sincere enthusiasm and appreciating our country's strength, I have confidence in the nation's ability to successfully and quickly deal with the present trouble. Therefore, with confidence, I naturally feel that the war ultimately must result in benefit to the electrical industries of the country. In the meantime, however, the indications are far from favorable to a continuance of the revival of business so recently noticeable.

Elihu Thomson, Lynn, Mass.: I can hardly consider myself an expert on the matter, but I should say that the probable effect of the war will depend upon the length of time it takes to finish up the war. I can only regard war as a destructive process, and even as a destructive process, and the ultimate effect can hardly ever, it seems to me, be a beneficial one, although the atmosphere may be somewhat cleared by the war.

S. M. Hamill, Brush Electric company, Schenectady, N. Y.: If the war lasts only a few months I do not believe that it will materially affect the electrical business. If however the naval war lasts a year or two, which is possible, it will have a very disastrous effect on the electrical business, which, with it so far this year, has been very large.

Mr. Edison and the Duluth Trip.

To the committee of invitation of the Northwestern Electrical association Thomas A. Edison is said to have stated on Monday that it was his desire to attend the summer meeting of the association to be held on the steamer Northland between Chicago and Duluth on June 10th to 13th. Mr. Edison assured the committee, it is reported, that unless something unforeseen occurred he would make one of the party.

Electric Power Companies and Their Relation to Municipalities.[1]

By A. E. Lang.

Consideration of the relation on the part of an electric-power company to the station producing the current on the one hand and to the community consuming it on the other opens a field of thought and discussion quite beyond the possible limits of a single paper.

I must therefore touch but briefly the outlines of this field, with the hope of suggesting question that will bring out an interchange of views along practical lines.

There is a two-fold object which must be accomplished: First, the investment of capital must be made profitable to the investors, and, second, the community must be served in the best possible manner at a minimum cost.

It was only about 10 years ago that electricity was found to be a practicable means of propelling street cars, and it has developed so rapidly, that it has been quite difficult to secure men familiar with the work. Indeed, the demand at one time was so great that men were hurried through the shops of the electrical works, having acquired but little practical knowledge, soon to blossom out full-fledged electricians—but in name only. As a result of this hasty and insufficient preparation, these so-called electricians in many instances made mistakes, which were costly indeed, but, nothing daunted, they forged ahead and succeeded in constructing and operating many miles of electric railway all over the country.

The insufficient knowledge of electricians was not only evident in the construction and equipment of the railways, but also at the power stations and the factories where the apparatus was manufactured. But notwithstanding the crudity of many things in the electrical line and the lack of knowledge in relation thereto, the public was bound to have it, and so power was purchased at enormous prices, a so-called electrical engineer was placed in charge, and the work carried on regardless of expense, and, I was about to say, of consequence.

I would say in the meantime, however, that could some of the owners of street railways using horse power, or some of the capitalists who ventured investment in the earlier electric-light plants, have foreseen the almost fabulous sums of money required to construct the same, and the long time they would have to wait—and may still wait—for profits, there would have been much more caution and much less progress.

Once started in motion, there was no convenient stopping place, and in many and many instances none has yet appeared. But we may say this is American—truly American.

What has been said applying specifically to the street-railway field is equally applicable to electric-lighting plants, so far as the power house, repair shop and overhead lines are concerned. Each furnishes power useful to the citizen, and each should be made profitable to its owners. Before long, as they are each closely related to the municipality, and the community expects and demands the best possible service at the minimum cost.

How can this be accomplished?

It rarely occurs to my mind that many existing street-railway and electric light companies have passed through very costly experiments with crude machinery they were forced to buy, and inexperienced and inefficient employes they were obliged to install and operate it. Finding that expenses were exceeding revenues, and grasping at every promising improvement offering greater economy, change after change has been made, and is still making, to reach better results, all of which have involved increasing capital stock and the issuing of bonds.

There was no other way to avert failure and avoid the sheriff, and thus many companies have gone forward loading pace upon which interest must be paid, and still the end is not yet. Every new plant installed possesses some new features that offer better service, with greater economy, and this forces existing plants to again remodel and create more debt and consequent increased interest charges.

It is plain that the cost to the consumer must remain unchanged, except in the few communities where the conditions mentioned have not so largely prevailed.

A condition such as this is, of course, unfortunate, both for the community and for the company, and no doubt leads to much discussion of the question of municipal ownership of these properties. Vainly believing that the cost of such service can be materially reduced, and profits proportionately increased, municipalities desire to reap supposed harvest. This I believe to be erroneous under present forms of society and government.

I do not believe that municipal ownership of such properties is wise in any sense nor that much will be done in this direction, especially not if private corporations keep pace with the best methods of service and offer reasonable rates.

I am one who believes that the community will deal with these corporations fairly, if the corporations will be equally fair with the community. Some corporations are too exacting—too much inclined to reap a harvest of quick return by way of dividends and provide a rapidly accumulating sinking fund to wipe out original investment.

This method, though Yankee-like and generally called business-like, is not a prudent or wise way of handling corporations depending on the public for their existence. A better way, it seems to me, is to take the public into your confidence, deal fairly and even generously with it, give the best possible service at the smallest profit consistent with a fair return on the investment and reasonable provision for meeting outstanding obligations and future depreciation, in which event the community will deal fairly with you.

Citizens should be made acquainted with all the conditions governing properties of this kind, should be informed of the reason for incurring the debts which generally exist and of the annual and contingent burdens we assume. Fulfilling these conditions, fair prices will usually be allowed for transporting passengers upon our railways and for power and light supplied.

Where the company is left free to fix its own prices, no advantage should be taken, but a reasonable and just charge should be made as indicated. The tendency of the present age is toward lower prices for labor as well as for the product of farm and factory and lower interest on money, and electric power companies must meet it.

To do this, no better method can be found than by consolidating under one roof all electric power companies where conditions are favorable. Re-equip with the latest and best types of machinery for generating current, rearrange circuits for better power distribution, introduce better lamps, repair and keep in good order all the apparatus appertaining to the street-railway and light plant. Give the best of service!

There is frequently no other way to do this than through consolidation, and this can be accomplished without criticism or objection on the part of the community, if the reduced cost to the consumer, with first-class service rendered.

Corporations, like individuals, sometimes make mistakes, and through miscalculating the expense of construction and operation or in the eagerness to secure grants, or for various other reasons, they assume contracts upon terms and at rates and prices too cheap to permit giving the best of service, with the result that great dissatisfaction is expressed by patrons and citizens agitated and the warfare between the city and company begins. Furthermore, when such corporations have reasonably profitable contracts, they are sometimes mismanaged by their avaricious owners; county service is rendered their patrons, and the result is the same.

Again, municipalities, in some instances, through the prejudice or political aspiration of their governing boards, seeking advantage by every method known to their officials, harass corporations, and thus force them to retaliate by giving poor service.

Now, gentlemen, do you perceive the call for your labor and efforts? It is here where your skill is in demand, here where it is your power to work out the problems which will aid in putting this class of property into more profitable operation, satisfactory to owners and the community.

The power house, repair shop, cars, track and lines are the dividend producers, when skillfully and intelligently contructed and operated, and are needed to carry on this work, needed now, perhaps, more than ever before, to pilot safely to a dividend basis plants of companies already existing—needed, also, to wisely inaugurate other enterprises of a similar nature, and thus extend still further the uses and advantages of this wonderful power.

The first consideration of every person as he enters the market to sell his labor, or to invest his money in commercial pursuits is how large a return can he obtain, either from labor alone, or from labor combined with the investment of capital?

Either field is legitimate and proper, but by far the wider is that open to labor, which is rewarded as reward, if the labor be of a higher order, is abundant and certain. Investment of capital with hope of great returns is speculative and uncertain. If returns are steady, they are usually moderate.

I know of no field more promising than the electrical. In it young men of energy, perseverance and devotion can make a good living, and perhaps acquire a competency.

I have briefly indicated some of the problems which will confront you when you have entered into active service. It is needless to say that you cannot be too well prepared to meet them. Your ability and education, however, are not the only qualifications necessary to possess in order to succeed. Without an honest and faithful and constant devotion to the interest of your employer, no permanent success will be attained.

You are now acquiring scientific and, as far as possible, practical information in electrical engineering. Some of you will be called to manage electrical properties, to finance them, to look after municipal, county or state legislation. The broader your information concerning the subject, the higher degree of usefulness you will attain. There is to the student every incentive for faithful, industrious work. The possibilities are unlimited and the reward ample.

---

[1] Lecture delivered at Purdue University, Lafayette, Ind., April 26, 1898.

The Water, Light and Power company of St. Cloud, Minn., has passed out of the hands of a receiver, and the company has been reorganized as the Gas and Electric company.

Chicago Edison Company.

The report of the Chicago Edison company for the year ended March 31st shows marked improvement in the condition of the central-station business of the city. The gross earnings were increased about eight per cent., while operating expenses were increased less than four per cent., and in proportion to gross earnings they are now the smallest in the company's history. An interesting comparison is made between the figures for the last fiscal year and those for the 15 months ended March 31, 1894, the latter including the whole World's Fair period. In the 15 months of 1893-94 gross earnings were $480,000 more than in the last twelve months, but operating expenses were $475,000 larger, so that in the last year the company earned practically the same amount net as in the 15 months ended March 31, 1894. In the last fiscal year the company's output of current was 70 per cent. greater than in the year 1894 and 15 per cent. greater than in 1896-7. This increase was accomplished, as shown, with an increase of only four per cent. in operating expenses, and during the year the price to the consumer was reduced, following out the company's well settled policy of intrenching against all possible competition by producing and selling current more and more cheaply. As to the growth of business in the last year, it may be added that the first six months of the year showed no increase over 1896. On the contrary there was a decrease. The last six months, however, showed enough increase to leave receipts for the 12 months $113,255 ahead. From 1894 on, the results achieved by the company are shown as follows:

Year ending March 31st.	Gross.	Optg.	Earned on stock.	Per ct. optg.
1895	$1 437,042	$953,377	$328,537	66 3
1896	1,461,084	898,517	404,432	61.5
1897	1,548,608	948,934	419,340	61 3
1898	1,661,863	985 338	449,844	59.3

The last year, as compared with the preceding year, shows larger earnings, reduced proportion of operating expenses and a larger surplus after dividend requirements were met. Out of this year's surplus $40,000 was charged to depreciation reserve. The figures of 1898 and 1897 are:

EARNINGS.

	1897-98.	1896-97.	Increase.
Gross	$1 661,863	$1,548,608	$113,255
Operating expenses	985,338	948,934	36,404
Net	676,524	599,674	76,850
Interest	226,680	180,334	46,346
Earned on stock	449,844	419,340	30,504
Dividends	398,072	397,518	554

The growth of the business during the year is shown by the following statement of business connected:

Incandescent lamps	259,496
Arc lamps	5,896
Motors (horse power)	8,415
Total equivalent in 16 candle power lamps, March 31, 1898	436,083
Total equivalent in 16 candle power lamps, March 31, 1897	355,140
Increase for fiscal year	80,943

The capital stock is the same as a year ago, but the company has issued $708,000 of the new bonds during the year. The proceeds went to improvement of plants, as that item increased $922,878. These are the only important changes shown by the balance sheet. The following gives all the items for two years, with comparisons:

ASSETS.

	March 31, 1898.	March 31, 1897.	Changes.	
Plants, real estate, etc	$9,553,208	$8,630,330	Inc.	$922,878
Work in progress, etc	161,549	136,405	Inc.	25,144
Accounts received	211,110	197,799	Inc.	13,311
Cash	86,826	206,541	Dec.	119,715
Open accounts	48,457	....	Inc.	48 457
Total	$10,061,151	$9,171,075	Inc.	$890 076

LIABILITIES.

	March 31, 1898.	March 31, 1897.	Changes.	
Capital stock	$4,975,900	$4,975,900		....
Bonds and debentures	4,458,000	4 750,000	Inc	$708,000
Accounts and notes payable.	279 213	131,066	Inc.	148,147
Open accounts	....	17,842	Dec.	17,842
Depreciation reserve	240,000	200,000	Inc.	40,000
Insurance fund	28,000	20,000	Inc.	8,000
Surplus	80,038	76,267	Inc.	3,771
Total	$10,061,151	$9,171,075	Inc.	$890,076

Depreciation reserve as here shown represents amounts charged out of earnings and set aside for permanent improvements to plants.

Philadelphia Electrical Exposition.

The Philadelphia Electrical Exposition company will give an electrical exhibition in its building, 818 and 820 Chestnut street, Philadelphia beginning on June 6th and continuing for one month. The building extends through to Sansom street and affords every facility to exhibitors to display their goods or machinery to the best advantage. In the center of the building there is a rotunda in which will be placed an electric fountain. A first-class orchestra will furnish excellent music, and no pains will be spared to provide all the conveniences necessary to insure the comfort and pleasure of visitors and exhibitors.

Various novelties of an electrical character will add to the genera[illegible] of the exhibition, and it is the intention of many of the prominent exhibitors at the New York exhibition to send their exhibits to the Philadelphia exhibition. Especial attention will be given to recent electrical inventions and to the exhibits of distinguished inventors when of an attractive character. The General Electric company will exhibit much of its apparatus of interest to the public. A working model showing the principle of Edison's magnetic iron-ore concentrating process will be shown; D. MacFarlane Moore will exhibit his recent form of vacuum-tube lighting, and many manufacturers have already signified their intention to exhibit.

Philadelphia is one of the best cities in the Union for such an exhibition, as generous support is always given by the residents to any first-class entertainment, to which can be added a large number of visitors from the neighboring towns. Great care will be taken in the selection of exhibits, none being admitted not germane to electricity. The building will be open from 10 a. m. to 11 p. m., and, with its accessibility, central location and the moderate admission fee charged, a large attendance both day and evening is expected.

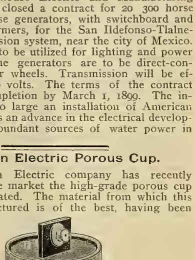
Intending exhibitors may obtain full information by addressing William D. Marks, the director, and diagrams showing location of spaces, together with other information, will be forwarded upon application.

Large Power Transmission Plant for Mexico.

The Westinghouse Electric and Manufacturing company has closed a contract for 20 300 horse power two-phase generators, with switchboard and raising transformers, for the San Ildefonso-Tlalnepantla transmission system, near the city of Mexico. The current is to be utilized for lighting and power in the city. The generators are to be direct-connected to water wheels. Transmission will be effected at 22,000 volts. The terms of the contract call for its completion by March 1, 1899. The introduction of so large an installation of American apparatus marks an advance in the electrical development of the abundant sources of water power in Mexico.

Western Electric Porous Cup.

The Western Electric company has recently placed upon the market the high-grade porous cup herewith illustrated. The material from which this cup is manufactured is of the best, having been



WESTERN ELECTRIC POROUS CUP.

subjected to a rigid test and stamped before being used. The upper portion of the jar is completely sealed, with the exception of two small vents for the escape of gas. All porous cups are stamped No. 6.

Tonawanda's Foresight.

The Niagara Falls Power company has just placed an order with the Westinghouse Electric and Manufacturing company for two transformers and the necessary apparatus for establishing a transformer station in North Tonawanda, which place is situated about midway between the Falls and Buffalo on the transmission line. Ever since the cables were strung through the Tonawandas, it has been the hope of the people there to profit by the nearness of the electrical power, and the awarding of the contract referred to is evidence that the Niagara Falls Power company has found customers there. The Tonawandas form the greatest lumber market in the country, and there are numerous factories and industrial establishments there that could, and probably will, use Niagara power to an advantage. As yet the site of the station has not been made public, but it is clear that Niagara's force is about to make captive another industrial center. When the franchise for the erection of the transmission line through the Tonawandas was granted, it was with rare foresight specified that the price to be charged for power there should not exceed 92½ per cent. of the lowest price charged for power in Buffalo for similar use, the argument being that there was less loss in transmitting power to the Tonawandas than there was to Buffalo, which is twice as far from Niagara Falls.

National Electric Light Convention, Chicago, June 7th, 8th and 9th.

The most popular line from Cincinnati, Louisville and all points South to Chicago is the Big Four Route via Indianapolis; magnificent sleeping cars and unequaled dining-car service. For maps, rates, etc., address E. O. McCormick, passenger traffic manager, Big Four Route, Cincinnati, O.

Government Contracts.

The following bids have been received by the public printer for furnishing and erecting seven electric elevators in the Government Printing Office at Washington, D. C.: Henry Vogt Machine company, Louisville, Ky., $11,901; Sprague Electric company, New York, $16,925; Otis Bros. & Co., New York, $15,480.

The secretary of the treasury has awarded the following contracts for the installation of an electric light and power plant in the United States postoffice building at Baltimore, Md.: Morton, Reed & Co., of Baltimore, $6,996 for the engines; Siemens & Halske Electric company, $4,558 for the dynamos.

The secretary of agriculture is considering proposals for furnishing the department with telegraph instruments, etc., during the next fiscal year.

Col. T. A. Bingham, in charge of the office of public buildings and grounds, Washington, D. C., is inviting sealed proposals until May 10th for furnishing electric battery supplies during the fiscal year which will begin June 30th. Information regarding the supplies required can be obtained upon application to the office.

CORRESPONDENCE.

New York Notes.

New York, May 2.—Everything is in readiness for the opening of the electrical exhibition at Madison Square Garden to-night. Chauncey Depew is expected to preside, at the invitation of Dr. Pupin, president of the New York Electrical society, and a large attendance is expected. The show has been extensively advertised, and its promoters are working hard for the success they deserve.

The Syndicate Construction company was recently incorporated with a capital of $50,000 to build and operate electric railroads in Union, Somerset, Middlesex, Mercer, Burlington and Camden counties in New Jersey. The incorporators are Gottfried Kruger and Andrew Radel of Newark, and Edward H. Radel of New Brunswick, all at present officers of the Brunswick Traction company. It is stated that the Brunswick Traction company has come to an agreement with the council of Somerville and will at once commence building an extension through the town.

A temporary injuction has been granted restraining the Kings County Traction company from parting with any assets of the Traction company, or with the right, title and interest of the Traction company in the capital stock of the Atlantic Avenue Railroad company. The proceedings were begun by Crowell Hadden, a shareholder of the Traction company.

M. S.

New England Notes.

Boston, April 26.—The Boston Elevated Railroad company has on exhibition at the rooms of the State Board of Railroad Commissioners very elaborate and comprehensive plans of the proposed routes. These are being carefully studied by real-estate owners and others who have a direct personal interest in the location of the elevated structure, and it is likely that the hearings to be held by the board on the question of approval will bring out a wide variation of opinions. It is the general opinion that the elevated company proposes to build a structure with the least possible delay, and of a character that shall embrace all that the most experienced engineers may suggest. On the question of an exchange of traffic between the elevated system and the new south station it is likely that some objection will be raised to the location of the proposed station across Atlantic avenue and on a line with Summer street. It will, no doubt, be strongly urged that some kind of a covered way, leading from this station to the big terminal, should be provided, if it is clearly shown that the number of passengers from the elevated to the terminal is likely to reach any considerable number. Expert opinion on this matter, so far as ascertained, is to the effect that the exchange will be of comparatively insignificant proportions.

It has been reported that the New York, New Haven and Hartford railroad was to equip about 10 miles of its Berkshire division with electricity, but an official of the company says that the plan has not been seriously considered. The part of the line referred to, forming a part of the old New Haven and Derby railroad, has a large passenger and freight traffic, and has been threatened in the last two Legislatures by parallel trolley schemes, one of which was with some difficulty defeated. It is a very vulnerable part of the New Haven system. The officer referred to says that, although it has but a single track, it can be operated both by electricity and steam by means of new sidings. In spite of this qualified official denial, the impression remains that the line may be equipped with the third rail in the near future.

C. S. G.

PERSONAL.

Mr. J. A. Colby, who for the last nine years has been general manager of the Edison Light company of Des Moines, Iowa, is spending a few weeks in New York. Mr. Colby will be remembered as one of the old Edison men, having been connected with the parent company some 12 years ago and also with the Sprague Electric Railway company. He is

well posted in the electric-lighting business, having had so many years of practical experience in the management of central-station work.

Mr. W. F. Osborne, for seven years the eastern representative of the Western Electrician, with office in New York, has resigned to become the business manager of the National Provisioner, a leading journal in the packing and provision trade. Mr. Osborne has given active, faithful and efficient service to the Western Electrician, and by his pleasing manners and personality he has made for himself a large number of warm friends among the electrical men of the East. Mr. Osborne's late business associates on the Western Electrician join with his other friends in wishing him a very complete measure of success in his new field of activity.

ELECTRIC LIGHTING.

G. S. T. Carnes of Memphis, Tenn., and H. H. Corson of Schenectady, N. Y., have franchise for the erection of an electric-light plant at Jackson, Miss.

ELECTRICAL SECURITIES.

The Erie Telegraph and Telephone company has declared a quarterly dividend of one per cent., payable May 7th.

The gross earnings of the Metropolitan Street Railway company of Kansas City from January 1st to March 31st were $1,614,270, against $1,466,827 last year.

The Brooklyn, Queens County and Suburban Railroad company reports for the quarter ended March 31st: Gross earnings, 1898, $162,664; 1897, $154,927; increase, $7,737; operating expenses, 1898, $104,589; 1897, $107,419; decrease, $2,830. The net earnings of $58,075 therefore showed an increase of $10,567.

The quarterly report of the Rochester Railway company shows a falling off in gross receipts of $8,669 and an increase of operating expenses of $1,086, as compared with the corresponding period last year, when, after paying fixed charges, there was $10,739 in the treasury. This year a deficit is reported of $54. The company's gross earnings this year up to March 31st amounted to $192,614.

The Long Island Electric Railway company reports gross earnings for March of $281,549, an increase of $20,070 as compared with the same month of last year, and net $36,726, an increase of $4,355. For the nine months ended March 31st the gross earnings were $3,480,261, an increase of $295,215 as compared with the corresponding period of last year, and net $1,061,887, an increase of $119,111. Fixed charges were $1,022,199, leaving a surplus of $136,948, an increase of $141,827.

POWER TRANSMISSION.

The correspondent of the Manufacturers' Record at Augusta, Ga., writes: "The Savannah River, a stream of varying moods, by turns loitering over the gentle slopes or tumbling over the rocky ledges, is capable of developing 400,000 horse power, according to an engineering estimate, from Trotter Shoals to the Augusta Canal, a distance of about 40 miles. The thriving little cities of Washington, Elberton and Hartwell, in Georgia, and Edgefield, Greenwood, Abbeville and Anderson, in South Carolina, can obtain all the power they require from this source for street railroads, electric lighting and industries by electrical transmission."

The Bolton Falls Electric company has been organized at Waterbury, Vt., to develop the Bolton Falls, 4½ miles north of Waterbury. On the Winooski River, at this place, there is a fall of 46 feet, and the power is estimated at 3,000 horse power. The company is now asking for estimates on water-wheels, penstocks, construction of dam and electrical equipment. Plans and information can be had from G. H. Almon, manager, at Montpelier, Vt. The company's directors are C. L. McMahon, Stowe, Vt.; G. H. Almon, Montpelier, Vt.; G. E. Moody, C. C. Warren and G. W. Randall, Waterbury, Vt. The following-named officers have been elected: President, G. E. Moody; vice-president, C. C. Warren; treasurer, C. L. McMahon; manager, G. H. Almon; clerk, C. D. Robinson

TRADE NEWS.

The Electric Arc Light company announces the removal on May 1st of its New York office to 120 Liberty street, the home of the Pioneer enclosed arc.

The Central Electric company of Chicago is carrying in stock all sizes of double and single, silk and cotton-covered magnet wire up to and including No. 40, and is prepared to meet all orders for these goods.

The Illinois Electric company announces that it has secured the Chicago agency for the 1898 type of Lundell fan motors, and is carrying a large stock of desk, bracket and ceiling fans. The Illinois company is doing an excellent business, not only in fans but in supplies generally.

The business of Jos. S. Wood, electrical engineer, of 25 Park Row, New York, and that of H. M. Shaw, manufacturers' agent, 126 Liberty street, in the same city, has been merged into that of the new firm of Wood, Shaw & Co., manufacturers, exporters and dealers in electrical specialties, with general offices at 40 Broad street, New York. The shops of the firm are fully equipped with machinery, tools, help, etc., for turning out the highest grade of work in the quickest time possible.

The Westinghouse Electric and Manufacturing company is to supply the electrical apparatus for the new plant of the Detroit, Ypsilanti and Ann Arbor Railroad company, consisting of four 300 horse power generators, three boosters, switchboards and ten car equipments, including 40 50 horse power motors.

The new catalogue issued by the Buckeye Electric company is being called for by lamp consumers in all parts of the country. The special coiled-filament Buckeye lamp is said to be the best that money and skill can produce. Western inquirers can write to J. H. Cooke, 753 Monadnock building, Chicago, for catalogue, prices, information, etc.

A charter has been issued to the George C. Towle Manufacturing company to manufacture electrical machinery at Lancaster, Pa. The directors are G. C. Towle, J. E. Hubley and R. Blickenderfer of Lancaster, Pa., G. A. Towle of Lowell, Mass., and J. P. Williams of New York. The company has the contract for making the Paragon fan and power motors for the season of 1898.

Designing engineers and power-house superintendents will find the new catalogue of power-transmitting machinery issued by the Falls Rivet and Machinery company of Cuyahoga Falls, O., a valuable one. It is clearly printed and illustrated, has an index and gives descriptions, dimensions and prices of pulleys, friction clutches, couplings, shafts, brackets, hangers and the like to the extent of 216 pages. The company has branch stores in New York, Boston and Cincinnati, and a branch office at 943 Rookery, Chicago.

The Electrical Exchange of Chicago reports great success with its new agency for the Midget Upton arc lamp. It has already secured orders for a large number of these lamps from all parts of the country. One shipment was sent to St. Michaels, Alaska. In addition to the regular line of Midget Upton lamps the Exchange is putting out a new Midget Upton alternating lamp, which is meeting with great success. The Exchange carries a full line of Midget Upton lamps in Chicago stock, and will be pleased to have prospective purchasers call and examine the various samples now on exhibition.

Attention is directed to the offer of the Ohio Electric Specialty Manufacturing company of Troy, O. This company will send to responsible persons any number of its own pure copper woven-wire brushes on 10 days' trial. If the brushes are not entirely satisfactory in every respect, the purchasers are requested to return them at the company's expense. This company has pursued this policy from the beginning of its business career, and the evident fairness of the proposition and the satisfactory results obtained from practical trials have gained for it a large and increasing trade.

The Fischer Foundry and Machine company of Pittsburg, under date of April 28th, issued the following statement: "The controversy between the Fischer Foundry and Machine company of Pittsburg, Pa., builder of the Fischer engine, and the Weston Engine company of Painted Post, N. Y., builder of the Imperial engine, regarding the infringement of certain patents relating to self-oiling engines, has been decided in favor of the Fischer Foundry and Machine company. This decision affects the majority of builders of self-oiling engines, and will probably result in a decided modification in the existing designs of this type of engine."

The Economic Power company of Rochester, N. Y., has in the last week placed orders with the American Tool Works company of Cincinnati, O., for a number of lathes, planers and milling machines. The American Tool Works company has also received orders through its office at Stockholm, Sweden, for a full line of engine lathes, ranging in swing from 14 to 30 inches, and through its office at St. Petersburg, Russia, an order for lathes, planers, shapers, drill presses and bolt cutters, which will be placed in the locomotive works at that place. Inquiries and orders from Mexico have also been coming in freely in the past three or four weeks, the company having booked a number of large orders from that country in the last week, among them being one from Compania Agricola del Tlahualita, at Zaragoza, Mexico, for a number of planers, lathes and shapers.

"Lightning Arresters" is the title of a short treatise, from the press of the General Electric company descriptive of the devices which that company has developed for preventing injury to electrical apparatus by lightning. The introduction is a short examination of the qualifications necessary to a perfect lightning-arrester, with a short disquisition on the special advantages of the magnetic blow-out. This is followed by concise descriptions of the arc and incandescent station arresters, already well-known as types "A," "AA" and "B." Greater space is given to the more recently developed lightning arrester for direct-current circuits up to 850 volts, and to the "G E" short-gap arrester, especially designed for alternating-current circuits and in use on almost all of the great electric power transmissions of the West. The booklet is well written and printed, the illustrations are excellent and the diagrams of connections clear and distinct. It is announced that "Lightning Arresters" will be furnished by the supply department of the General Electric company on application at any of the sales offices.

The proper lubrication of gas-engine cylinders has been a difficult problem. The problem, however, seems to have been successfully solved by an official of the Pennsylvania Railroad company. He writes as follows: "I had a gas engine at Sharon, Pa., running a pump, and the man that had charge of it allowed the lubricator to run dry and cut the piston, piston rings and cylinder. The makers of the gas engine said the cylinder would have to be sent to the shop and bored out and a new piston put in. It was our busy season and we could not do without water. I had some of Dixon's finely pulverized graphite, and I commenced to feed it into the cylinder through the suction pipe with the air and gas, with immediate relief. After about two weeks the engine was running smoother and using less gas than ever before. I had this same engine apart last Saturday, and every place that was cut is smooth as glass. This one instance saved us about $75. I have great faith in this graphite and always keep it on hand."

The Chicago Fuse Wire and Manufacturing company, whose factory was totally destroyed by fire on January 28th, is now in better condition than ever before for filling orders for tested fuse wire and links. This company calls attention to the fact that after the first of May all its fuse wire will be packed on the trademark spools which it has used for the last five years, and that these spools will in turn be inserted in neat individual tin boxes, which will protect the wire from danger of abrasion and also from being affected by changes of temperature. The company will carry a full stock of all sizes of wire, strip, links, telephone and telegraph fuses, and will make shipments from the factory in Chicago or its eastern office at 853 Broadway, New York city, as may be most convenient to the trade. W. R. Goodman, the manager, says that the great consideration shown to the company by all its friends in the trade during a few weeks of enforced suspension of business after the fire is highly appreciated.

BUSINESS.

The Berlin Iron Bridge company of East Berlin, Conn., has just completed for the Conway Electric Street Railway company, at Conway, Mass., a steel bridge to carry its electric line across the Deerfield River. This bridge is about 300 feet in length.

The Technic Electrical Works of 214-218 New street, Philadelphia, has issued "pocket price-lists" of knife switches and isolated-plant switchboards. These folders contain not a little information, compactly arranged, and are convenient for the pocket.

The Jandus enclosed alternating arc lamp shows an average efficiency, it is claimed, of 95 per cent. It burns singly on the same circuit with incandescent lamps, and gives a steady and brilliant light, with noiseless mechanism. The Chicago office is at 753 Monadnock building.

The book of general information and catalogue of telephone supplies issued by the Farr Telephone and Construction Supply company, 357 Dearborn street, Chicago, contains much valuable information and will be found of great assistance to all interested in telephone exchanges.

The well-known house of John A. Roebling's Sons company, which has a Chicago store at 171 Lake street, has issued a booklet on telephone cables and their equipment and installation. The pamphlet contains much useful information for the telephone-construction man, including useful hints, with drawings, on the splicing of joints.

The Western Electric company has designed fan motors that are to be connected up directly with 220 or 550-volt circuits without the intervention of any resistance. This company also states that three of its 110-volt motors or two of its 220-volt motors can be run in series on 550-volt circuits, and the 550-volt motor can be placed on 600-volt circuit.

The new observation car on the New Pennsylvania Limited is the finest car of the kind. It leaves Chicago Union Station 5:30 p. m. daily over Pennsylvania Short Lines. The Allegheny Mountains are crossed by daylight, and present an imposing sight from the observation room or open observatory. For particulars apply to H. R. Dering, assistant general passenger agent, 248 South Clark street, Chicago.

J. E. Keelyn, president of the Western Telephone Construction company of Chicago, has just closed a deal for control of the Graham Electric company's telephone and switchboard business as well as all of its patents. It is said this is the fifth concern that has been arranged for in like manner recently. A strong combination seems to be imminent, with Mr. Keelyn as president, and a strong financial syndicate backing it.

The Packard mogul lamp continues to stand alone in the field, it is claimed, as the largest successful incandescent lamp. The trade has settled down quite generally to the 300 candle power size, and this is now being used very extensively for lighting where large units are required. It is an interesting fact that a large number of the first mogul lamps that were made several years ago are still burning and giving good service.

The Central Electric company, Chicago, is n

troducing a new and ingenious device for ceiling clusters, consisting of a porcelain block with a metal canopy, which attaches directly to the ceiling, having the sockets embodied as a component part of the fixture. The clusters are furnished in various sizes from two to five lights and are especially designed for street-car work. Special circulars relating to this device can be had on application.

The New Vancouver Coal company, Nanaimo, British Columbia, has ordered a 175 horse power engine from the Ball Engine company, Erie, Pa., for electric mining purposes. The Chappell Chemical company of Hegewisch, Ill., will have an electric-light plant. A Ball engine furnishes the power. The American Ordnance company, Lynn, Mass., has ordered, through J. H. Houghton, Boston agent of the Ball Engine company, Erie, Pa., a 125 horse power engine for use in government work.

Problems of special difficulty have been solved by the Westinghouse Electric and Manufacturing company in the construction of the apparatus recently shipped for the works of the Carborundum company of Niagara Falls. One thousand horse power is supplied at voltages varying from 80 to 300. The work involves special difficulties on account of the wide range of voltage and the very large currents carried. The apparatus as designed by the Westinghouse staff is of high efficiency and power factor.

During the warm weather it is necessary to make places of business cool enough to enable the occupants to accomplish their usual amount of work and to do it in comfort. For this purpose it has been found that the Western Electric 1898 desk and bracket-fan motors are excellent. Their convenient size, three speeds and good mechanism (all of which are described in detail in Bulletin 2-F, issued by the Western Electric company) make them most desirable. A copy of Bulletin 2-F will be mailed to anyone requesting it.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued April 26, 1898

602,872. Process of Producing Chemical Compounds by Electrolysis. Joseph W. Richards and Charles W. Roepper, Bethlehem, Pa. Application filed July 6, 1897.

The process described consists in passing an alternating current through electrodes of similar composition immersed in an electrolyte, one or more of whose constituents forms alternately at each electrode, by electrolytic attack thereon, a compound partially derived from the consumption of that pole, which is insoluble in either the electrolyte or the products formed at the opposite pole for the time being, and which is precipitated from the electrode of consumption.

602,873. Process of Electrolytically Manufacturing Metallic Sulphides. Joseph W. Richards and Charles W. Roepper, Bethlehem, Pa. Application filed July 6, 1897.

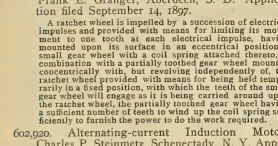
The process of manufacturing pure metallic sulphides consists in employing an anode of or containing the metal or metals whose sulphide is desired in a solution containing a hyposulphite salt as an electrolyte in conjunction with any suitable cathode, passing a current of electricity therethrough and precipitating the sulphide of the metallic base present in the anode.

602,895. Electrical Selector. Louis W. Crofoot and Frank E. Granger, Aberdeen, S. D. Application filed September 14, 1897.

A ratchet wheel is impelled by a succession of electrical impulses and is provided with means for limiting the movement to one tooth at each electrical impulse, having mounted upon its surface in an eccentrical position a small gear wheel with a coil spring attached thereto, in combination with a partially toothed gear wheel mounted concentrically with, but revolving independently of, the ratchet wheel provided with means for being held temporarily in a fixed position, with which the teeth of the small gear wheel will engage as it is being carried around upon the ratchet wheel, the partially toothed gear wheel having a sufficient number of teeth to wind up the coil spring sufficiently to furnish the power to do the work required.

602,920. Alternating-current Induction Motor. Charles Steinmetz, Schenectady, N. Y. Application filed February 12, 1897.

The method of compensating for the self-induction and magnetizing current of an alternating-current motor con-



NO. 602,895.

sists in inducing from the secondary of the motor leading currents in a tertiary closed circuit in inductive relation to the secondary motor-circuit.

602,921. Alternating-current Induction Motor. Charles P. Steinmetz, Schenectady, N. Y. Application filed February 12, 1897.

The method of starting and running an alternating-current motor, consists in passing alternating current through a primary winding, generating thereby a current in a secondary winding, inducing by the joint action of the primary and secondary windings an electromotive force in a tertiary winding, and causing the current in the tertiary winding to lead the electromotive force.

602,922. Electric Arc Lamp. Elihu Thomson, Swampscott, Mass. Application filed November 4, 1897.

Carbon-feeding mechanism is employed, together with a thermo-electric expansive device and a series electromagnetic controlling apparatus responsive to variations in the current passing through the lamp governing the operation of the thermo-electric expansive device.

602,923. Trolley. James E. Wells, Syracuse, N. Y. Application filed May 1, 1897.

A contact frame comprising sides arching in opposite directions, cross bars connecting them, one side having a longitudinal groove in its upper face or edge, and the other having a rigid longitudinal flange and a rolling contact mounted between the sides, combined with a suitable trolley arm upon which frame is mounted.

602,925. System of Electric Metering. Herbert C. Wirt, Schenectady, N. Y. Application filed December 31, 1897.

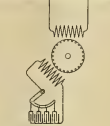
In a multi-rate electric meter there is the combination of a motor mechanism for registering the consumption of energy in an electric circuit, a recording mechanism which governs the speed of the motor mechanism, and means for altering the retarding or braking effect to change the rate of registration during coal in portions of the day.

602,950. Electric Massage Appliance. Fred J. S Lan, Kansas City, Mo. Application filed July 23, 1897.

A medical battery is attached to a device resembling a pressing iron, having a handle connected thereto, and a smooth roller mounted within the frame, and fluted rollers also mounted within the frame, together with a plate interposed between the fluted rollers and carrying a sponge, and a separate disk, one wire from the battery being attached to the plate and the other wire to the disk.

602,953. Electric Luminous Alphabet and Board for Same. Daniel M. Moore, Newark, N. J. Application filed December 17, 1895.

An illuminating character consisting of a translucent hollow vacuous receptacle is provided with hollow, lateral, recurved, extending projections in combination with separated terminals of an electric circuit adapted to removably hold one or more of the characters.



NO. 602,921.

602,963. Distribution of Electric Currents. Elihu Thomson, Lynn, Mass. Application filed December 6, 1886. Renewed February 26, 1898.

The main or principal circuit is supplied with rapidly varying electric currents, and there is also a local or independent circuit with an induction apparatus placed between the mains and the local or independent circuit, reaction coils in the primary circuit of the apparatus, and means for varying the number of coils in which the reaction is set up without short-circuiting them.

603,027. Rheostat. Roscoe W. Ney, New Rochelle, N. Y. Application filed February 5, 1897.

The apparatus comprises a suitable supporting frame, end pieces, and two bars which connect the pieces together, a metallic strip secured to the upper end piece, and to which is attached a binding-post; and the resistance strips, combined with suitable contact pans to which the ends of the resistance strips are secured, but which contact pans are electrically separated from each other. The binding post and the connecting strip connected to the post, and a switch which has its edge to pass under the ends of the contact pans.

603,041. Electrostatic Generating Machine. Adrian H. Hoyt, Penacook, N. H. Application filed August 9, 1897.

One claim is given: In an electrostatic generator, the combination with the terminals for the working circuit of spark-gap arms adapted for longitudinal and rotative adjustment within their posts.

603,042. Hinge Connection for Electrical Measuring Instruments. Adrian H. Hoyt, Penacook, N. H. Application filed November 1, 1897.

An electrically connected hinge is described comprising a stationary member composed of two blocks of metal joined by a hollow shaft or cylinder, one of the blocks having a small perforation or socket near the opening leading to the hollow shaft, a movable member having an arm projecting from its edge adjacent to the stationary member provided near its outer end with a lateral projection fitting the small socket in the stationary member, a copper ribbon passing spirally around the hollow shaft and having its ends soldered or otherwise rigidly attached one to the shaft and the other to the movable member, and set-screws threaded to perforations in the stationary member and communicating with the opening in its shaft.

NO. 602,963.

603,050. Incandescent Electric Lamp. Mark W. Dewey, Syracuse, N. Y. Application filed July 22, 1891.

The combination is claimed of a carbon filament with a receiver made entirely of glass and completely inclosing the filament, and from which receiver the air has been exhausted, and a coiled electric conductor outside of the receiver and in inductive relation to the inclosed filament.

603,058. Electrical Retort. Hilliary Eldridge, Daniel J. Clark and Sylvain Blum, Galveston, Tex. Application filed June 28, 1897.

Apparatus for manufacturing hydrogen gas by electrolysis comprises a retort having an insulated cover, an upright frame clamped to the retort and provided with a guide head and a stuffing box mounted on the cover and having insulating bushings in line with the guide head, combined with an anode passing through the guide head and stuffing box, a feed mechanism for the anode, a cathode and electrical connections for the anode and cathode.

603,060. Electric Railway. Charles F. Holtmann and Charles Bergmann, Pittsburg, Pa. Application filed August 5, 1897.

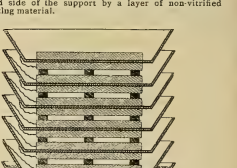
A series of separated successively arranged contact boxes, a fixed interior metallic contact plate arranged longitudinally within the bottom of each box and provided at its ends with upwardly disposed contact lugs or projections, a normally spring-elevated, straight-track section arranged longitudinally above each box, each track section being of a U-shape in cross section and carrying a depending connecting post, and a horizontal contact bar fitted between its ends to the lower extremity of the connecting post and provided with oppositely-located pairs of keeper plates adapted to engage with the contact lugs or projections.

603,061. Device for Turning off Commutators of Dynamos or Motors. William H. Jordan, Brooklyn, N. Y. Application filed January 28, 1897.

A tool is carried by a rotating and longitudinally movable shaft, a bearing for the shaft adjustable toward and away from the commutator, a driving wheel adapted to be journaled on either end of the bearing and by means of which the shaft is rotated and through which driving wheel the shaft is longitudinally movable, and a driving connection between the wheel and the commutator.

603,063. Rheostat. Harry W. Leonard, East Orange, N. J. Application filed July 28, 1896.

A support is covered by a layer of partially vitrified insulating material with a layer of vitreous insulating material on the first layer, and a conductor held to the insulated side of the support by a layer of non-vitrified insulating material.



NO. 603,229.

603,069. Electric Cable. Nathaniel G. Warth, Indianapolis, Ind. Application filed October 25, 1897.

This cable has its dielectric composed in part of fabric or like solid insulating material, and in part of compressed insulating gas confined for service as a dielectric.

603,112. Electric Lamp. David Misell, New York, N. Y. Application filed October 9, 1897.

An improved electric lamp comprises a casing, a battery carried thereby, a lamp in connection with one of the poles of the battery, a bowed-spring contact plate in connection with the other pole of the battery, and a handle in operative connection with the lamp and the spring contact plate, whereby a positive circuit connection against jarring or jolting is provided.

603,184. Electro-pneumatic Piano Player. Fred R. Goolman, Los Angeles, Cal. Application filed May 5, 1897.

The inventor describes an air-duct bridge, comprising a block channeled with parallel air-ducts, each duct having a lateral opening communicating in an enlarged recess covered by a flexible diaphragm, and electrical contact points arranged outside the diaphragm and adapted to be brought into electrical connection by the bulging or lateral movement of the diaphragm from pneumatic action.

603,198. Electrically Propelled Vehicle. Henry G. Morris and Pedro G. Salom, Philadelphia, Pa. Application filed September 29, 1896.

The front axle has a motor mounted thereon, and a forward structure forming part of the vehicle body is located directly above the front axle and carries the battery.

603,229. Storage Battery. Edward A. Barber, Watertown, N. Y. Application filed September 13, 1897.

The asphalt coverings for the series of superimposed metallic trays are described, the independent positive plates resting on the bottom of the trays, insulators across the positive plates, negative plates resting on the insulators, combined with the independent electrical connection between each of the plates and the side of the adjacent tray, which connections are wholly immersed in the electrolyte.

Western Electrician.

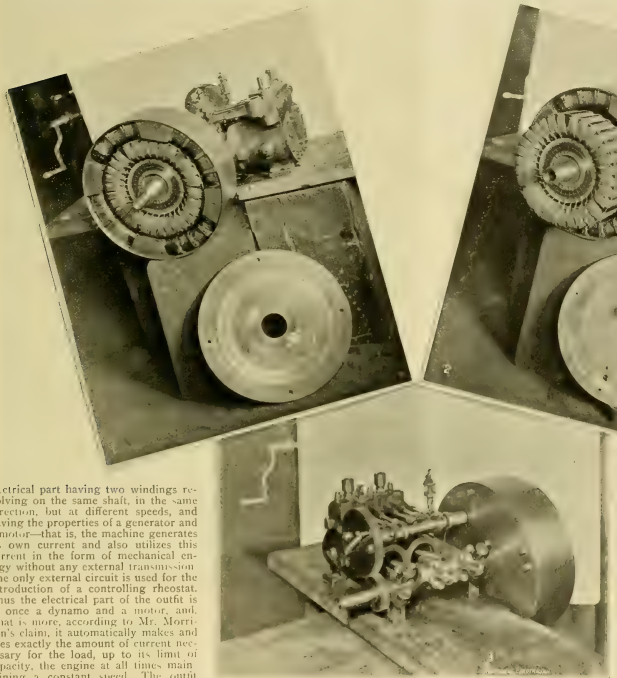
EVERY SATURDAY.

Vol. XXII. CHICAGO, MAY 14, 1898. No. 20

Morrison's Apparatus for Power Conversion.

William Morrison, the Chicago inventor, whose work is especially well known in the line of storage batteries and electric carriages, has devised the apparatus which is illustrated by the group of pictures given herewith. These pictures are reproductions of three photographs of the same machine, showing it complete, ready for operation (Fig. 3), and also with the inner electrical parts displayed (Figs. 1 and 2). The machine is small, but its operation involves an interesting electrical principle. It consists of an engine of about four horse power, adapted to be operated by gasoline, oxy-hydrogen or oil, and an electrical part having two windings revolving on the same shaft, in the same direction, but at different speeds, and having the properties of a generator and a motor—that is, the machine generates its own current and also utilizes this current in the form of mechanical energy without any external transmission. The only external circuit is used for the introduction of a controlling rheostat. Thus the electrical part of the outfit is at once a dynamo and a motor, and, what is more, according to Mr. Morrison's claim, it automatically makes and uses exactly the amount of current necessary for the load, up to its limit of capacity, the engine at all times maintaining a constant speed. The outfit was built for vehicle propulsion, but it may be adapted for other purposes. The objection will arise: Conceding that the electrical design is correct, why burden the machine with the electrical part at all, as the power can be used direct from the engine shaft to the driving axle of the vehicle? In answer Mr. Morrison contends that experience has shown that the starting torque, great flexibility and ease of control of the electric motor are necessary to the satisfactory operation of horseless carriages. To obviate the weight of storage batteries he generates the current on the vehicle by a light prime mover, and as a comparatively heavy balance wheel would be needed in any event for an explosive engine, he takes advantage of the fact by making his flywheel, in effect, the electrical generator and motor. Thus the weight of the generator and motor is practically saved.

The outfit as shown in Fig. 3 weighs about 200 pounds, and, as stated, it has a capacity of exerting about four horse power. The gas engine has twin cylinders, side by side, 3½ inches in diameter and 3½-inch stroke. At full speed it operates at 600 revolutions per minute. An ingenious centrifugal governor, designed by Mr. Morrison, is placed on the inside of the larger gear-wheel shown in Fig. 3, and automatically controls the speed of the engine. The gear-wheel is geared to the engine shaft and of course increases in speed with it. When the speed increases beyond the point for which the retaining spring is adjusted, the centrfugal force causes the governor to fly outward, and through the medium of a series of cams and rollers on the shaft driven by the large wheel the exhausts in the ignition chambers are opened and the engine takes nothing but air until the speed of the engine is again reduced. This regulation automatically establishes the speed of the engine within narrow limits during the period of its operation. The engine is water jacketed, and will be muffled in service on vehicles. It is designed to run at constant speed during the trip of the vehicle, whether the latter is going fast, slow or standing still.



MORRISON'S APPARATUS FOR POWER CONVERSION

The bronze cylinder shown on the right in Fig. 3 and uncovered in Figs. 1 and 2 embraces the electrical part of this interesting apparatus. The cylinder itself, with the outer coils, which may be called the field magnets, revolves at the constant speed of the engine, being securely keyed to the main shaft. The shaft extends through the cylinder. Mounted upon it is a Gramme ring armature, with a commutator within it. The armature is simply slipped on the shaft and is free to revolve upon it. The heads of the cylinder are fiber plates. The outer one, shown removed and below the machine in Figs. 1 and 2, is provided with copper contact rings for the rheostat connection on the outside (Fig. 1) and carbon brushes adapted to make contact with the commutator and wiring connections on the inside (Fig. 2). If the armature of this machine were held stationary, it would simply be a direct-current dynamo with revolving field-magnets having a capacity of about 15 amperes at 170 volts. If the armature were not held back in any way it would adopt its natural tendency to follow the revolving fields and no current would be generated at all. But Mr. Morrison has attached the load of the driving gear of the vehicle to the armature shaft—not to the fixed-speed field-magnet and engine shaft—and so the armature is retarded in its natural tendency, generating a varying current, as the armature wires cut a greater or lesser number of lines of force. In utilizing this tendency of the revolving armature to "catch up" with the faster revolving field coils, but always held back, more or less, when the load is on, lies the kernel of Mr. Morrison's invention. But it will be interesting to have an explanation in his own words:

"Assuming the carriage to be at rest, the armature of the transmitting mechanism is also stationary. Notwithstanding this fact, the prime mover may continue to revolve the field about the armature.

"It is a well-known principle in ordinary dynamo machines that as the speed of the armature is increased the current generated increases, and as the speed decreases the current decreases.

"When the vehicle is at rest the armature of the apparatus is stationary, and in starting, after the electric circuit is closed, the greatest current is generated and the greatest pull exerted upon the armature by the field, which force is transmitted to the carriage through the connection between the carriage and the armature. This results from the fact that in starting the field revolves about the stationary armature at approximately the highest rate of velocity. When the resistance of the carriage is overcome, in starting, the armature commences to rotate in the same direction as the revolving field, and the current generated and pull exerted then depend upon the relative difference of speed be-

tween the armature and the field. As the speed of the armature gradually increases the relative difference of speed between the armature and field decreases, the current generated decreases, the energy exerted diminishes and consequently the speed of the carriage, connected with the armature, increases. This continues until the resistance of the carriage, now under way, and the pulling force or energy of the apparatus becomes equal, when the carriage is then driven at its highest speed. Under conditions of unobstructed, level roadway, the field revolves about the armature at such a relatively greater speed as to generate a current and consequent energy sufficient to propel the carriage at the highest rate of speed.

"When the resistance of the carriage is increased by a grade or other obstacle, the speed of the carriage and the speed of the armature connected therewith is decreased, and as the field revolves about the armature approximately at a constant rate of speed, the relative difference of speed between the field and the armature is increased, thus increasing the current generated in proportion to the increased resistance of the carriage, and in consequence energy is exerted sufficient to overcome this increased resistance of the carriage."

Mr. Morrison makes provision for a rheostat in circuit with the field and armature to vary the speed of the carriage and to open and close the circuit at will. He claims to have done away with the use of a motor as a separate machine, but to have combined the advantages of the light gas engine and the flexible electrical system. Any suitable means of transmitting the power of the armature to the driving axle of the vehicle may be employed.

Electrical Plant at the Paris Exposition.

Recent statements make it appear that the electrical generating plant at the Paris Exposition of 1900 will be of 26,000 horse power, or somewhat smaller than that at the World's Fair at Chicago in 1893. The lighting will be entirely electrical and will enable all the buildings to be open after dark. The amount of current required for this purpose will necessitate machinery of 15,000 horse power. Then, again, it is proposed to have all the machinery, wherever exhibited, in motion, and the necessary driving power for this purpose will be electricity, for the production of which another 5,000 horse power will be required. Two buildings will be devoted to the boilers. In the one will be boilers of French origin and in the other those of foreign make, and a comparison of the work done by them will not be the least interesting portion of the exposition to engineers.

New York Electrical Exhibition.

The close of the first week of the electrical exhibition in Madison Square Garden, New York, found the show complete, in the sense that all the preparatory work had been done and also in the sense of worthily representing all the varied applications of electricity. The two features which were the last to be in readiness were the illuminated fountain and the illuminated cascade. The work on these features was interrupted by the accident which befell Thomas A. Edison, Jr. Mr. Edison, while erecting the cascade at the rear end of the garden, fell and injured his left hand and arm. But he recovered from the hurt sufficiently in two days to again supervise the work in person.

Beside these attractive features there are many interesting "show" displays, such as the illuminated tower, the tank in which is demonstrated the explosion of submarine mines for the destruction of warships, the Edison magnetic ore concentrator, the Moore exhibit of vacuum-tube lighting, the theatrophone, the generating plant, display of historical tableaux and experiments in "wireless" telegraphy.

The show is given under the auspices of the New York Electrical Society, of which Dr. M. I. Pupin is president and Mr. George H. Guy secretary. The members of the society have worked hard for the success that has been attained. So have Mr. C. O. Baker, Jr., the president of the Exhibition company, Mr. Marcus Nathan, the general manager, whose experience in the previous electrical exhibition has been the groundwork for the success of the present enterprise, and Mr. T. C. Martin, the chairman of the auxiliary and educational committee.

One of the really instructive exhibits is the large and prominent display made by the Edison Electric Illuminating company of New York, which shows many of the applications of electricity to industrial and household purposes. The spectacular vacuum-tube lighting display arranged by D. McFarlan Moore is also interesting and impressive. Its principal feature is a small chapel lighted from a vaulted roof which has arches made of the glass tubes. All of the tubes—16 arch and three ridge tubes—are connected in multiple are between three wires. The common or positive wire extends along the ridge, while each of the two negative wires extends horizontally along the sides of the chapel back of the side fixtures, which rest on top of the pilaster caps from which the tube arches spring. The three wires enter the top of a polished oak cabinet, which contains all of the light-controlling apparatus and is situated on one side of the entrance passageway.

Signaling Through Space.

A year ago but few people were aware of the fact that it was possible to signal through space without the aid of wires, but for many years it was well known to scientists that this had been accomplished for short distances. Last summer Mr. Marconi, a talented young Italian student, following in the pathway of Lodge, Branly and other experimenters, found that it was possible to transmit signals through space to a distance of over 10 miles. Mr. Marconi accomplished this wonderful result by means of some slight changes in the arrangement of well-known apparatus, and also by using at the transmitting and receiving stations a perpendicular wire suspended from a high point in the air. But while Marconi has accomplished much, an American inventor has designed apparatus which is suitable for practical use, without constant attention to fine adjustment. Mr. W. J. Clarke of New York city has invented this new system, and the exhibition of his company in Madison Square Garden certainly pays a high tribute to Mr. Clarke's inventive ability.

In the center of the south gallery is placed the transmitter, which is contained in an insulated glass showcase and consists of a suitable storage battery which is connected to a specially constructed induc-

NEW YORK ELECTRICAL EXHIBITION.—LOOKING NORTH FROM TWENTY-SIXTH STREET SIDE.

tion coil placed immediately above it, the current from the battery, however, first passing through an automatic circuit-breaker placed in front of the battery. This circuit-breaker takes the place, for exhibition purposes, that a telegraph operator would when repeatedly calling "N. Y.," "N. Y.," "N. Y.," "N. Y.," which is the well known telegraph call for New York city. It will be seen, therefore, that the primary circuit of the induction coil being interrupted in this manner, the secondary or sparking circuit of the coil will also work intermittently in response to the workings of the primary, so that the sparks coming from the secondary of the coil, instead of being the ordinary continuous four-inch sparks, will alternate with each other in such a manner that anyone standing by the case and listening to the sparking can readily recognize the Morse signals "N. Y." "N. Y." "N. Y." This, however, does not complete the entire transmitting apparatus, as the secondary terminals of the coil are connected to what is known as the Clarke electrical oscillator, which consists of two large brass balls placed about ¼ quarter of an inch from each other, and also two smaller balls placed about a half inch from the larger ones. The secondary terminal of the coil being connected to the smaller balls, the sparks will pass these sparks passing in this way produces violent across between all of the four balls, and the fact of

electrical oscillations, which in turn generate invisible electric waves which go out into space in the form of ever-increasing spheres, something in the same manner as the widening ripple in a pool of water if a pebble is dropped in. These spheres have the power of passing through any material, the walls of a building or a crowd of people presenting no appreciable impediment to the passage of the waves. In the center of the north gallery is the Clarke receiver, the most essential part of which is known as the coherer. This little coherer is a most interesting piece of apparatus, and consists of a glass tube in which are fitted two sliding plugs of metal, so arranged that the distance between them in the center of the tube is adjustable, the space between the plugs being filled in with a prepared metallic powder. This powder when lying in its normal condition presents a very high resistance to the passage of the electrical current, often amounting to over 20,000 ohms. When the electrical waves from the transmitter strike this little coherer its resistance instantly decreases, often reaching as low a point as six or seven ohms. This return to their high resistance, when the local circuit is instantly opened, and the telegraph sounder gives its up click, or if a bell is used it instantly ceases to ring. Mr. Clarke's exhibit is so well adjusted that a large six-inch vibrating bell placed in the case containing the receiver is continually ringing out the Morse signals "N. Y.," "N. Y.," "N. Y.," and attracting universal attention by its wonderful performance. There is no material connection whatever between the transmitter and the receiver. In fact the electric waves do not seem to be interrupted in the least by the iron pipes which are used for the fountain in the center of the Garden, or by the large crowds of people which continually surround the apparatus. In order, however, that this perfect working can be secured it is necessary to connect one side of the receiver and one side of the transmitter to the earth, the other side of each of these instruments being connected to a brass rod about 10 feet in length which is hung from insulated supports, and which does not touch any conductor in any way whatever.

Mr. Clarke states that the apparatus has reached such a high state of perfection, that he is ready to transmit a message between New York and Chicago at any time when he receives an order for the necessary outfit. In doing this, however, it will be necessary to have an instrument in every town upon the way, and these instruments would respond to the signals sent out by the operator at any one of them in the same way as an ordinary telegraph.

The system promises to be of value to the American army and navy, and they are already placing orders with Mr. Clarke for his apparatus, which is so designed and constructed for this particular use that its method of operation is only known to those using it.

In the center of the Garden is placed a large tank of water, and in this tank four times each day Mr. Clarke blows up a miniature warship, which is blown into splinters by the mere pressing of a button on the transmitter in the south gallery, no connection whatever being made between the transmitter and the tank. A coherer however, is placed at the edge of the tank connected with a short wire running upward into the air.

NEW YORK ELECTRICAL EXHIBITION.—LOOKING EAST FROM MAIN ENTRANCE.

enormous decrease in resistance allows the current from the single cell of dry battery to pass through the magnet coils of a telegraph relay which is placed in circuit with the coherer. The relay magnets by their magnetism then pull up the armature, and this armature in its turn makes an electric contact which closes the local circuit of the apparatus, and clicks an ordinary telegraph sounder, rings a large vibrating bell, fires a cannon or mine, starts or stops a steam engine, or does anything that can be accomplished by a slight current of electricity.

When the waves have acted upon the powder in the tube it still remains at its low resistance point, and therefore it would be impossible to send more than one signal, were it not for the fact that at the same time that the relay armature closes the local circuit it also throws a strong battery current through a pair of magnets which operate a vibrating hammer. This hammer continually vibrates against the glass tube as long as the local circuit is closed. The tappings of these vibrations against the tube tend to shake up the powder, and cause it to return to its former high resistance, but as long as the waves are coming in from the transmitter, the filings are not perceptibly affected by the tappings. The instant, however, that the waves cease coming, the tapping shakes up the filings, and they immediately

Some of the Exhibits.

The Silex Insulation company of New York shows a new wiring conduits, which are administratively described as insulated, indestructible and incombustible.

A. W. Koenig is in charge of the Faries Manufacturing company's exhibit.

The John A. Roebling's Sons company shows all kinds of wires and cables, and the gentlemen in attendance at the exhibit receive their friends in a handsomely furnished parlor.

The Adams-Bagnall Electric company of Cleveland has a full line of arc lamps for all voltages and current, both in plain and ornamental finish. C. W. Phipps, the eastern manager of the company, spends much time at the exhibition.

A fine display of the MacIntire arc lamps is made by the International Arc Lamp company. One very striking feature is a pendant of 37 lamps in the center of the building. The lamps in this "arcolier" are lighted simultaneously by one service switch. They aggregate 40,000 candle power and weigh 1,500 pounds. Other lamps attract attention in various booths and about the building. Several of the booths of the electrical journals contain the MacIntire lamps.

The booth of the International Correspondence Schools of Scranton is very attractive. A picture of the school buildings, five by seven feet in size, surrounded by electric lights, showing the picture off to great advantage, hangs at the back of the booth. All engineers and electricians attending the exhibition who desire to obtain a technical education in engineering or electricity will find it interesting to visit this booth.

A beautifully dressed figure of the Goddess of Liberty is an attractive object in the booth of J. Jones & Son of New York. The rear wall of the booth is occupied by a handsome exhibition board, which displays a sign in miniature lamps, with switches, brackets, etc. Telephone bells and circuit breakers are shown on panel boards, and the exhibit also includes a switchboard complete. Other supplies and heating apparatus are displayed on counters. A neon arc lamp is shown in connection with a clock, which automatically turns the current on and off at set times.

The National Carbon company's exhibit is in charge of Richard O'Connor and M. H. Mead. It shows a complete line of carbon products, such as

which can be seen all sizes and shapes of telephone transmitter parts. In this line are shown carbon diaphragms as thin as .008 of an inch. A full line of all the battery cells manufactured by this company is shown, and its special gas-engine cell is exhibited for the first time. All sizes of round carbons, from one-eighth inch diameter up to six inches (the latter being the largest round carbons ever exhibited), are shown. Attention is called to the great facilities of this company for producing carbon of all kinds for experimental work. Several members of the company expect to be on hand at times during the show to renew acquaintance with their electrical friends.

H. B. Coho & Co. represent among other concerns at the exposition the Eddy Electric Manufacturing company and the Warren Electric Manufacturing company. They have in operation a 75-kilowatt improved Warren alternator, working 1,100 and 100 volts off the same machine, run by an Eddy direct-current motor. They also represent the American Rheostat company, Milwaukee, Wis.; Crown Woven Wire Brush company, Salem, Mass.; Diamond Electric company, Peoria, Ill.; Van Horne, Burger & Co., Dayton, O.; Translucent Fabric company, Quincy, Mass.; Otis Electric company, New York; Marietta Manufacturing company, Marietta, Pa., and the Pennsylvania Electric company, Philadelphia. In addition to the above companies, they exhibit a full line of switchboards, panel boards, etc. The exhibit is under the management of T. W. Kloman.

The exhibit of the Safety Insulated Wire and Cable company is one of the most novel at the electric show. The center of this space is occupied by a large tank showing "A Night Scene off Sandy Hook," with the use of Safety cables. The background is a painting of the numerous government works, showing Fort Hancock and the light-houses. In the fore-

FIG. 1. EXPERIMENTS ON COMMUTATION IN DYNAMOS AND MOTORS.—DIAGRAM OF CONNECTIONS.

ground, floating gracefully at anchor, is a United States battleship with her searchlight in active operation. To the right is Gedney Channel, with the Henry electric-buoy system in minature; the red and white electric lamps mark the course of the channel. Numerous torpedos, illustrating the connection and operations of the submarine defenses of New York harbor, are placed in the bottom of the tank. A section of a submarine cable of over 32,000,000 circular mils and a fine six-inch disappearing gun are also features of the exhibit. Mr. L. F. Requa, the general manager of the Safety company, is represented by Mr. Ira W. Henry, Mr. A. P. Eckert, Mr. L. R. Clark and Mr. H. T. Richards.

In the exhibit of the Fort Wayne Electric corporation perhaps the most prominent feature is an 80-light Wood arc dynamo of the latest type operating series arc lamps of 2,000 candle power each. The machine is equipped with an improved reversible regulator, complete on the dynamo, remarkable for its simplicity and accuracy. All wall controlling devices and outside regulator connections are dispensed with. This dynamo is driven by a direct-connected multipolar motor. A 37½-kilowatt Wood alternator of the low-frequency type is operated by a direct-current motor and supplies current to alternating-current arc lamps. There is also a five horse power single-phase, synchronous, alternating-current motor capable of starting under full load from a single-phase circuit, without the introduction of phase-splitting coils, condensers or other complicated auxiliaries. A commutator truing device, which is shown, is a simple tool, operated by hand, for facing the commutator perfectly true with the bearings. Small motors, transformers, meters and switchboard panels complete the exhibit, which is in charge of F. A. Wunder, assisted by T. A. Nathans.

Burhorn & Granger of New York and Philadelphia are exhibiting in operation a nine by 12-inch Woodbury high speed engine direct-connected to a 25-kilowatt Eddy generator. This engine is of the latest improved type and is equipped with the Shepherd governor, with which a regulation of one half of one per cent. for all variations of load is guaranteed, and also with an automatic oiling system to which the exhibitors invite attention. The regulation can be tested by visitors with the aid of a recording tachometer at the exhibit. Another portion of the space is taken up by a sectional model of the Woodbury cylinder and steam chest showing the Woodbury valve, the method of adjustment and means of providing for entrained water. This portion of the exhibit proves very interesting to visitors, who are thus enabled to see the inside of an engine of the same size and type as the one in operation. Attention is called to Burhorn & Granger's exhibit by a revolving illuminated sign. The firm distributes an attractive souvenir card on which announcement is made of the various houses which it represents, including the Stearns Manufacturing company of Erie, Pa., Harrisburg Manu-

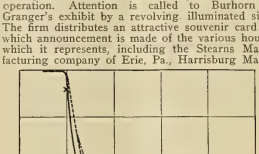

FIG. 2. EXPERIMENTS ON COMMUTATION IN DYNAMOS AND MOTORS.

facturing and Boiler company of Harrisburg, Pa., Philadelphia Engineering Works, Philadelphia Pa., and the Union Iron Works, Erie, Pa.

The Partridge Carbon company of Sandusky, O., is represented by Mr. Partridge himself, who presents to the general trade for the first time his new electric-light carbon for enclosed arcs, which the company claims to be equal to, if not better than, the imported carbons now in the market. Mr. Partridge had a number placed in several of the different enclosed-arc lamps. Tests were made on a Nowotny lamp at 110 volts and 4½ amperes and on one of 220 volts and 2½ amperes, and from all accounts the results were a great surprise to the enclosed-arc lamp people, as they claim it has been heretofore impossible to procure an American-made carbon suitable for this trying service. It is interesting to state, too, that a representative of the Western Electrician recently witnessed a test of these carbons under Manager Speer of the Partridge company at the Soldiers' Home in Sandusky, and the results were certainly such as would warrant an investigation of the merits of these new carbons of the Partridge company by electric-light men of this country interested in finding an American-made carbon suitable for enclosed-arc lamp service. Mr. Partridge received many congratulations on his success at having accomplished such fine results after his two years of hard work. In addition to exhibiting this special electric-light carbon, Mr. Partridge made a display of the well-known Partridge self-lubricating motor and generator brushes.

Experiments on Commutation in Dynamos and Motors.[1]

By W. H. Everett, B. A., B. E., and A. H. Peake.

The theory of commutation in dynamos and motors has been treated by various writers, but there seems to be room for further verification and help from experiment. We therefore give here a short account of some work in this field, on which we have

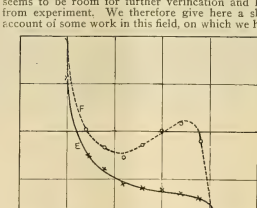

FIG. 3. EXPERIMENTS ON COMMUTATION IN DYNAMOS AND MOTORS.

from time to time been engaged. The experiments have been carried out in the electrotechnical laboratory of University College, Nottingham, where Prof. W. Robinson has kindly afforded us every facility.

Our work so far has been confined to a Crompton two-pole, compound-wound dynamo, with ring armature, designed to give up to 45 amperes at 110 volts when running at 1,610 revolutions per minute. It has 60 sections in the armature winding, each of six turns of wire 0.09 inch in diameter; the commutator segments being 7-32 inch thick on the face, and separated by 1-32 inch of mica. The resistance from brush to brush is 0.12 ohm, or 0.008 per section. The overall diameter of the armature is 7⅝ inches, and the net cross-section for the magnetic flux is 12 square inches. Throughout these experiments separate excitation, generally at about 100 volts, has been employed, without the series winding.

Referring to any direct-current dynamo or motor, the current is reversed in each section while passing under either brush, and thus the curve connecting current and time, for a given coil, consists practically of a straight line above and parallel to the time axis, followed by a straight line at the same distance below. The current cannot change abruptly, and hence these two straight lines must be joined by a curve, giving the current in the coil at each instant while it is passing under the brush. It is to this curve that we have given most attention.

Passing over various pioneer experiments, it will be enough to describe the arrangement we are now using (Fig. 1). We employ a special split brush, consisting of two copper plates, 0.036 inch thick and 1.6 inches wide, separated by vulcanized fiber, the overall thickness being about equal to that of the face of a segment. These plates are joined by a non-inductive resistance of 0.007 ohm, to the middle of which the positive main is connected. The negative brush is an ordinary one, covering about one segment and a quarter. From the ends of the resistance wires are brought to the terminals of a condenser, and in this circuit is included a revolving contact-maker, which completes the circuit at any desired instant in every revolution of the armature. The condenser is thus charged to the voltage existing between the ends of the resistance for any selected position of the armature coil under the brush; and this voltage is found by discharging the

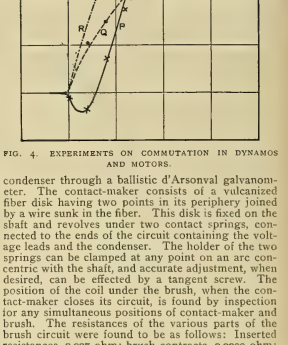

FIG. 4. EXPERIMENTS ON COMMUTATION IN DYNAMOS AND MOTORS.

condenser through a ballistic d'Arsonval galvanometer. The contact-maker consists of a vulcanized fiber disk having two points in its periphery joined by a wire sunk in the fiber. This disk is fixed on the shaft and revolves under two contact springs, connected to the ends of the circuit containing the voltage leads and the condenser. The holder of the two springs can be clamped at any point on an arc concentric with the shaft, and accurate adjustment, when desired, can be effected by a tangent screw. The position of the coil under the brush, when the contact-maker closes its circuit, is found by inspection or any simultaneous positions of contact-maker and brush. The resistances of the various parts of the brush circuit were found to be as follows: Inserted resistances, 0.007 ohm; brush contracts, 0.0022 ohm; armature section, 0.0088 ohm; total, 0.0174 ohm. These tests were made with a current of 15 to 20 amperes. The total with the ordinary brush was about 0.0088 ohm, or say half of the other.

It is necessary to consider the effects, on the commutation current-curve, of the modifications present in our split brush. Any features due to contact resistance of the brush should be known nearly unaltered in our curve, for such resistance is mainly operative only when a segment is just coming under the heel of the brush or just leaving the toe, and the middle part of an ordinary brush is therefore, in this respect, comparatively idle. The diminished thickness of the brush probably has the effect of slightly smoothing down the first and last parts of the curve, since it diminishes the range of commutation. As regards the insertion of resistance in the brush, one effect of this is to decrease the time constant, thus making the slopes in our curves, on the whole, steeper; but in any case, so far as this point is concerned, the curves hold good for a similar armature wound with wire of half the present gauge.

The general character of the curves admits of a simple explanation and agrees with the predictions of Mr. Housmann in his suggestive remarks on W. B. Sayers' first paper (Journal of Institution of Electrical Engineers, 1893, p. 490). In a motor, as a coil approaches the neutral axis, the electromotive force is in such a direction as to oppose the current—that

1. From the London Electrician.

is, to aid its reversal; and when the coil has passed the neutral axis, the electromotive force tends to oppose reversal. Hence to obtain reversal the brush should be moved to such a position as will bring the neutral point near the toe. It follows that the slope of the curve is greatest at first, and afterward decreases. In a dynamo the field required for reversal (since the current is in the opposite direction to that in a motor) lies in front of the neutral axis, and consequently the neutral point should be near the heel. This will give curves of the character shown. It should be remembered that the neutral axis is not fixed, but tends to move with the brushes if the lead is altered, though not to the same extent. Whatever current there is in the coil just before leaving the brush must be altered to half the armature current by the increase of contact resistance between brush and segment. Any excessive inaccuracy of finish will give rise to sparking.

Since at the neutral point no electromotive force is acting in the short-circuited coil, the current must there be diminishing, for an instant, at a rate—

$$\frac{di}{dt} = -\frac{R}{L}i,$$

where R is the resistance in the coil circuit and L is the inductance. Inserting approximate values for R and L, the neutral point can be found by inspection in each case. Generally it is near a horizontal part of the curve.

The curves shown in Figs. 2, 3 and 4 are each the average of four or five taken in succession, the average being taken as follows: Each individual curve was drawn rigidly through the points found; eight equidistant points were then taken in each curve, and the averages of the respective ordinates taken and plotted to give the curve shown. The scale in each case is so chosen that half the armature current is represented by the same ordinate. The brushes were always adjusted to avoid sparking. Figs. 2 and 3 show commutation curves for the machine used as a motor. The three curves in Fig. 2 show the effect of varying the current only; the brush position, speed and excitation being kept constant. As the current is increased the curves become flatter, and the first drop is not so great. This is what would be expected. Curve E in Fig. 3, compared with curve B in Fig. 2, shows more gradual reversal of the current due to weaker field. Curve F in Fig. 3, compared with curve B in Fig. 2, shows the result of moving the brush forward by half a segment. The first drop in the curve is not so great; the rise begins earlier and a greater change in the current has to be produced by the increase of contact resistance as the segment leaves the brush. Although this change is about 10 amperes, only very slight blue sparks were noticeable at the toe of the brush, showing that the current must have been raised almost to the half armature current before the circuit was broken.

It was found that a large change in the speed had little effect on the curves.

In Fig. 4 are shown three representative commutation curves for the machine driven as a dynamo. Curve P shows the increase of current at first, which is obtainable at light loads, and also excessive reversal. Curve R shows the gradual falling off in the rate of reversal as the current approaches the value demanded by the electromotive force. It also shows a change of current produced by contact resistance. This change must have been complete, for no appreciable sparking was produced; in fact, the experimental brush stood the heavy current of 45 amperes quite as well as the other brush.

COLLECTED DATA FOR THE CURVES

Curve	Armature current	Voltage on field.	Revs. per min.
A	6 5	100	420
B	12 0	100	430
C	17 5	100	600
E	19 0	50	650
F	12 0	100	440
P	6 6	100	820
Q	11 0	100	470
R	45 0	100	820

With a field excitation of 43 volts, a speed of 760 revolutions per minute and an output of 20 amperes, a curve was obtained very similar to curve R. This excitation gives about 45 per cent. of the flux with 100 volts. The reciprocal of the speed, since there are 60 commutator segments, is the fraction of a second in which the commutation is effected, and this is represented by the abscissa of the curve.

We hope to examine the subject of commutation further, as time permits. Instead of our present brush, we think of using a triple brush having three resistances meeting at a point; this, though not so simple, would remove the restriction as to brush thickness. Again, it would be instructive to find commutation electromotive force curves, say by means of thin coils over the armature winding, using instantaneous contact. Experiments with the machine used as a rotary transformer (for which purpose six slip rings are already fitted) would likewise be of interest. And we hope also to study commutation in a machine with toothed armature core.

W. A. Seevers has sold his interests in the electric-light and street-railway plant at Muscatine, Ia., to Harry W. Huttig.

Regulation of Compound-wound Dynamos.

The action of the Edison Electric Light company against the E. G. Bernard company and others has been decided in favor of the defendants and the bill dismissed. The action was instituted by the General Electric company and was defended by the Siemens & Halske company. It was based upon the patent, No. 264,668, granted to Thomas A. Edison, September 19, 1882, for an improvement in regulating the generative capacity of dynamo-electric machines. The defense in this suit was the invention and patent of Brush, which preceded any work of Edison on commercial dynamos, and which the court has found anticipated the Edison patent. The opinion of the court which accompanies this decision is of great importance to all manufacturers of dynamo-electric machinery. It has been maintained by those interested that if the Edison patent had been sustained, it would have subordinated practically all the generators for electric-railway and direct-current electric-lighting work in the United States.

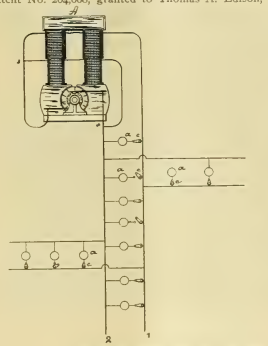
The cuts which accompany this article and to which reference is made in the opinion are reproduced from the specifications, one from the Edison patent and the group of five diagrams from the Brush patent.

The opinion is here presented in its entirety, as it forms an important and interesting chapter in the history of American electrical invention.

UNITED STATES CIRCUIT COURT,
Northern District of New York.

Edison Electric Light Company vs. E. G. Bernard Company *et al.* } Final hearing. In equity

This is an equity action, founded upon letters patent No. 264,668, granted to Thomas A. Edison,



REGULATION OF COMPOUND-WOUND DYNAMOS EDISON PATENT, NO 264,668.

September 19, 1882, for an improvement in regulating the generative capacity of dynamo-electric machines. The specification says:

The object of this invention is to produce means by which the addition or removal of translating devices in the multiple-arc circuits of a system of electrical distribution shall cause immediately a proper regulation of the current energizing the field magnet of the dynamo electric machine supplying such system, and this without the use of adjustable resistances, or of any mechanism whatever, except the ordinary circuit controllers of the lamps.

Of the drawing the specification says:

A is a dynamo-electric machine, from which lead the main conductors 1 2, in multiple-arc circuits from which are placed lamps or other translating devices, a, each provided with a circuit controller c. The lower portion of the field-magnet of the generator A is wound with wire, forming part of the multiple-arc circuit 3 4, from the main conductors 1 2. This circuit is of high resistance, so that only a small amount of current sufficient to primarily energize the field magnet will pass through it. It may, if desired, be a circuit supplied from an external source instead of from the conductors 1 2. The main conductor 1 is brought up on one side and wound around the magnet, afterward extending out parallel with the conductor 2 When translating devices are first put in circuit the magnet is sufficiently energized by means of the circuit 3 4, but as their number is increased the resistance of the main circuit is lowered, so that more current flows through the conductor 1 and the magnet becomes more and more energized. As devices are thrown out and the resistance of the main circuit increases, the energy of the magnet is lessened by the decrease of current in the conductor 1.

It will thus be seen that the regulation of the machine is accomplished instantly and automatically by the throwing in and out of circuit of single translating devices, the addition or removal of each device having an immediate effect on the current passing through the field magnet.

The claims are:

1. The combination, with a dynamo-electric machine and translating devices arranged in multiple arc, of a field circuit of constant resistance for primarily energizing the field magnet, and another field circuit whose resistance is varied by the addition and removal of translating devices, substantially as set forth.

2. The combination, with a dynamo-electric machine of one of its main conductors forming a portion of the coils of its field magnet, a circuit for primarily energizing such field magnet and translating devices arranged in multiple arc or derived circuits, whereby the addition of each individual translating device causes a corresponding increase in the energy of the field magnet, substantially as set forth

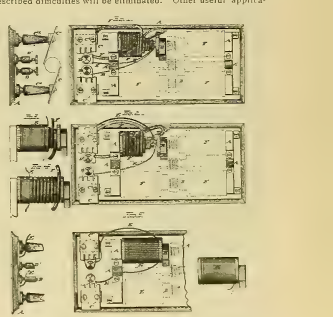
3. The combination of a multiple-arc circuit containing a portion of the coils of the field magnet of a dynamo-electric machine, a multiple-arc circuit containing the armature of said machine, and multiple-arc circuits containing lamps or other translating devices, all such multiple-arc circuits being derived from the same main conductors, and another field circuit whose resistance is varied by the addition and removal of translating devices, whereby the addition or removal of any translating device causes an instant and corresponding regulation of the current energizing the field magnet of the machine, substantially as set forth.

The earliest date assigned for the conception of the Edison invention is August 19, 1879. The machines made at the time of the patent, and prior thereto, did not operate in a satisfactory manner. They never were a commercial success. They have disappeared.

On the 22d of July, 1879, letters patent, No. 217,677, were granted to Charles F. Brush for an improvement in dynamo-electric machines. The application for this patent was filed March 11, 1878. Brush says in the specification:

My invention relates to dynamo-electric machines, and has for its object the maintenance in such machines of a "magnetic field" while the machine is running, whether the external circuit is closed or open.

In dynamo-electric machines as ordinarily constructed no magnetic field is maintained when the external circuit is open, except that due to residual magnetism; hence the electromotive force developed by the machine in the condition is very feeble. It is only when the external circuit is closed through a resistance not too large that powerful currents are developed, owing to the strong magnetic field produced by the circulation of the currents themselves around the field magnets. Such machines are not well adapted to certain kinds of work, notably that of electroplating. For this purpose a machine arranged to do a large quantity of work at one operation may fail entirely to do a small quantity, because of the comparatively high external resistance involved in the latter case and the low electromotive force of the machine at the start. Again, it is well known that during the process of electroplating, a very considerable electromotive force is developed in the plating bath in a direction opposed to the current from the dynamo-electric machine. If now the current from the machine is momentarily weakened, by accident or otherwise, its magnetic field, and consequently its electromotive force, are correspondingly reduced. If the latter falls below the opposing electromotive force of the bath, it will be overcome by it, and the machine will have the direction of its current reversed. This accident often happens with plating machines, and is a source of much annoyance. It will now be obvious that if even a moderately strong magnetic field be constantly maintained within the machine, both of the above described difficulties will be eliminated. Other useful applications of a "permanent field" machine will readily suggest themselves.



REGULATION OF COMPOUND-WOUND DYNAMOS — BRUSH PATENT, NO 217,677.

I attain my object by diverting from external work a portion of the current of the machine, and using it, either alone or in connection with the rest of the current, for working the field magnets. I prefer the latter plan of the two just above mentioned, especially for electroplating machines. If, now, the external circuit be broken entirely, the magnetic field will in the former plan just mentioned remain unimpaired, and in the latter plan will remain sufficiently strong to effect the desired end

In applying my invention to dynamo-electric machines, I wind the cores of the field magnets with a suitable quantity of comparatively fine wire having a high resistance in comparison with that of the external circuit and the rest of the wire on the machine. The ends of this wire are so connected with other parts of the machine that when the latter is running a current of electricity constantly circulates in said wire, whether the external circuit be closed or not. The high resistance of this wire prevents the passage through it of more than a small proportion of the whole current capable of being evolved by the machine therefore the available external current is not materially lessened When this device, which I have called a "teaser" is used in connection with field magnets, also wound with coarse wire, as shown in Fig. 1 of the drawings, for the purpose of still further increasing the magnetic field by employing the main current for this purpose, in the usual manner, then the teaser may be so arranged that the current which passes through it will also circulate in the coarse wire, thus increasing the efficiency of the device This arrangement, illustrating one of the [illegible] applications of my inventions is shown in Fig 1 of the drawings.

Instead of the teaser and helix I being constructed from wire of different gauges, the size of wire may be alike in both [illegible] the teaser wire may be coarser than the principal magnet wire but in these cases the waste of current through the teaser would be excessive, leaving comparatively little for use in the external circuit.

Instead of the magnet being surrounded with both teaser and ordinary helix I, the latter may be omitted, and the teaser increased in gauge and length thus still maintaining its high resistance until it will of itself maintain sufficient magnetic field This modified form of machine is shown in Fig [illegible] of the drawings.

After explaining the drawings he says:

It should be distinctly understood that I do not limit my invention to the form adaptable to any particular dynamo-electric machine [illegible] susceptible of a variety of modifications whereby it may be applied to devices of various constructions without any material departure from the spirit and intent of the essential principle of its construction and operation

Eastern Office: 809 Postal Telegraph Bldg., New York.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished or application.

American manufacturers have established their reputation in England, and they are now engaged in pushing their wares in Germany with the same vigor that marked their course in Great Britain. The facilities of the American manufacturers as compared with foreign companies are illustrated in the following cablegram from Berlin: "Twenty American electric street cars were recently delivered in Berlin and 100 more have been ordered. They were wanted quickly, and therefore the order was placed with an American firm that was able to deliver them in Berlin at the same price and in about one-fourth of the time required by German manufacturers." Wherever enterprise and good workmanship are prized American products are bound to win.

In view of the recent interruptions of the cable service and the present interest in everything pertaining to international telegraphy, it is worthy of note that "the Spanish government issued just before the war a decree which gives certain privileges to Spanish and foreign vessels as long as they are used exclusively for the purpose of cable-laying or maintenance, and provided that they do not carry any cargo other than cables and apparatus necessary for their work. These vessels are practically made free of custom dues. All that is required is a statement signed by the captain showing the occupation of the vessel and the stores on board. The Spanish authorities are enjoined to give every assistance in their power to further the work of these vessels." The attitude of Spain toward submarine cable enterprises has not been uniformly friendly in the past.

In view of the hostile attitude of the daily newspapers of Chicago and a considerable portion of the community to the policy of the street-railway companies, it is said that these corporations are seriously considering the advisability of establishing a mail and express route from Whiting, Ind., to Evanston, Ill., in order to place their properties beyond the control of the city council. It is proposed to lease the lines of the South, West and North divisions of the city to the Chicago General Railway company, which is incorporated, not under the "horse and dummy" act, as are the other roads, but under the "steam railroads" act. The same rights are claimed for the Chicago General as are enjoyed by the Northwestern and other roads using city streets. After a mail service is put in operation it is claimed all the lines over which the cars run will become post routes and pass under federal jurisdiction. Any attempt on the part of the city to take possession or tear up the tracks on the expiration of the franchises, according to the projectors, will incur liability to prosecution in the federal courts. Another reason for running cars from Whiting to Evanston is to give the route terminals in two states, bringing it, if possible, within the jurisdiction of the Interstate Commerce Commission. The right to lease other lines is granted to the West and South Towns railway, which is a part of the Chicago General system. It is proposed to carry only mail and packages on the through cars, thereby obviating competition between the several lines.

Not long ago a spirited discussion in Congress attracted the attention of the country to a number of prominent industrial enterprises, including several electrical companies, that were said to enjoy special privileges through legislative and governmental concessions. These corporations were denounced as monopolistic institutions and they were charged with exerting a pernicious influence at Washington. Probably as a result of this stirring up, Senator Cannon has introduced a resolution for the appointment of a Senate investigating committee, consisting of the present committee on manufactures, to find out and report to the Senate whether there are combinations or trusts in manufacturing circles in the United States, whether they are fostered by the existing tariff law, whether they are to the public advantage, whether their character is such as to bring them within the scope of the prohibitory laws, and, if so, why they are not prosecuted and dissolved. The reasons ascribed for introducing this resolution are that it has been publicly charged that certain manufacturers of the United States who are engaged in interstate commerce have entered into combinations to control the manufacture and sale of certain articles of general consumption, and that they are protected by law against competition from foreign manufacturers. The contention is made by the advocates of these trusts that their effect is to cheapen the cost of manufacturing, and, as a result, to cheapen the cost of such manufacture to the people. It is not probable that action will be taken on a resolution of this character at the present time, but it is significant of the general attitude of the people toward combinations.

In England the National Telephone company occupies a position somewhat similar to that enjoyed by the American Bell Telephone company in this country for many years. It virtually controls the telephone business of the country, and, like all corporations of the kind, it has many enemies who are actively engaged in opposing the granting of additional privileges or the perpetuation of present conditions. The company is now under fire, and a parliamentary investigation of the conditions of the service is expected. A comprehensive report of the recent discussion on this subject in the House of Commons was printed in the Western Electrician on April 23d. It showed that there had been much objection and complaint, resulting in a public demand for the acquisition of this business by the government as a branch of the Postoffice Department.

The statement of the company's position, made by its representatives at the annual dinner of the staff of the corporation, will be read with interest in this connection. It was announced that during the last year 90 new exchanges had been opened, making a total of 800 in working order, and the number of subscribers had increased by 12,000. The company courted the fullest inquiry, and it was believed that the judgment of experts would be that the service was as cheap and as efficient as it was possible to make it, considering the great difficulties with which the company had to contend. It was admitted that the great municipalities had recognized the commercial advantages of this means of communication and had enabled the company to make great strides in placing wires underground, and bringing the plant into efficient condition. The familiar claim was made that where facilities have been afforded the National telephone service compares favorably with that in any part of the world. Comparing the telegraph and telephone services it was pointed out that by means of the latter, 430,000,000 of effective messages were sent last year, while the telegraph system sent 73,000,000. The comparison with the work of other countries was even more favorable. Germany, with a population of 52,000,000, had 107,000 subscribers; while England, with a population of between 38,000,000 and 39,000,000, had 106,000 subscribers; that is, there was one subscriber in every 300; in Germany, 1 in 400; in France, where there were 30,000 subscribers, 1 in 1,200; in Austria, 1 in 1,500; in Belgium, 1 in 680, and in Holland 1 in 1,000.

Like the Bell company in this country, the National company in England is clamoring for exclusive privileges. It abhors competition and desires to be credited with assuming a philanthropic attitude in preventing capitalists from risking their money in such undesirable investments as opposition companies. The position of the National company was concisely stated by its spokesman on this occasion as follows:

Competition in this business is an impossibility. Telephony is a service which from its very nature is an imperial service and therefore a monopoly.

Those who are not under the spell of the National company in England, like those outside the circle of Bell influence in this country, will require something more substantial than such statements. The evidence of prosperity of the independent movement in this country is to be found everywhere. It may be possible that the National company fears similar development in Great Britain, and rather than enter such a contest it would welcome action by the government tending to the acquisition of its plant, especially if this could be done on the same basis as the establishment of the government telegraph system.

WAR NEWS.

Chicago Volunteers for Brigade of Engineers.—The task of forming a Brigade of Engineers, which was assumed by Captain Eugene Griffin of the General Electric company, is being pushed forward rapidly and systematically, and the assistance of many prominent workers in the electrical field has been enlisted in all parts of the country.

The Chicago Electrical association, at its last meeting, on May 6th, discussed this subject and determined to actively assist in the formation of the brigade. Lieutenant F. B. Badt explained the requirements of the service and several communications from Captain Griffin to B. E. Sunny were read. The project has been favorably indorsed by the War Department and the matter has been sent to Congress, as it is necessary to have a special bill to authorize the organization of a Brigade of Engineers "from the nation at large." The Senate has passed such a bill and the House probably will take similar action. In the meantime the secretary of war has asked Captain Griffin to raise a regiment of engineers, and it is believed that the experience gained in this way will be valuable for the larger force, and that it will be comparatively easy to expand the regiment into a brigade by building up each battalion into a separate regiment.

A committee composed of Thomas G. Grier, W. B. Hale and R. F. Schuchardt was appointed by the Chicago Electrical association to assist in the work in Chicago and vicinity.

Application blanks in the following form have been prepared for distribution among Chicago engineers, with the request that they be filled out and forwarded immediately to B. E. Sunny, Monadnock building, Chicago:

I hereby tender my services to the Government of the United States in the present war with Spain, for the term of 2 years, unless sooner discharged.

I am a ..... by trade and wish to join the Volunteer Engineering Corps in any capacity whatever.

Name: .....
Address: .....
Occupation: .....
Married or single: .....
Age: .....
Former military experience if any: .....
.....
Tropical experience if any: .....
.....
Do you speak Spanish? .....
Date: ..... 1898.

Following is a list of those who have signified their intention of entering the service in Chicago: J. W. Carroll, Charles R. Willitt, Paul M. Clemens, William Norrie, Hy. Mouronbali, Gail H. Browne, Frank C. Horn, J. C. Baird, Robert Zimbee, John J. O'Mara, John P. Leighton, George W. Ford, R. C. Huston, George Frederickson, David Angus, C. Gustafson, John M. McDougall, John J. Delaney, Fremont Hill, Timothy J. Davey, Henry J. Schell, C. W. Boynton, E. A. Mellinger, Eugene Klapp.

Many engineers throughout the Northwest have signified their intention of joining, including the following-named: Isador S. Jezewska, Winona, Minn.; G. S. Ellsworth, Madison, Wis.; P. D. Cunningham, Green Bay, Wis.; Charles L. Tindell, Dubuque, Iowa; Henry E. Elliott, Escanaba, Mich.; C. F. Burgess, Madison, Wis.; Fred J. Pratt, Champaign, Ill.; Jas. Morgan, Kansas City, Mo.; William J. Sullivan, Marengo, Ill.; V. K. Hendricks, Terre Haute, Ind.; Richard Palmer, Joliet, Ill.; H. H. Meyer, Davenport, Iowa; Clark R. Fickett, Elgin, Ill.; Thomas A. E. Cunningham, Battle Creek, Mich.; K. Ettner, South Bend, Ind.; H. L. Chipps, Champaign, Ill.; Clifford Cooling, Woodstock, Ill.; W. O. Sampson, Waukegan, Ill.; Fred A. James, S. F. Case, Milwaukee, Wis.; Thomas H. Carver, Valparaiso, Ind.

Recruiting offices have been opened in New York, Boston, Philadelphia and other eastern points, and it is anticipated that there will be no trouble whatever in securing the necessary men for the service.

Captain Griffin first broached the subject of forming an Engineers' Brigade, as noted in the Western Electrician of April 16th. In a letter to Secretary Alger Captain Griffin suggested that a volunteer Brigade of Engineers, not exceeding 3,500 men, be regularly enlisted and commissioned in the service of the United States, to consist of three regiments, each organized as follows: one colonel, one lieutenant-colonel, three majors, one lieutenant and adjutant, one lieutenant and quartermaster, six lieutenants, adjutants and quartermasters of the three battalions, one sergeant major, one quartermaster sergeant, 12 companies, A to M inclusive, 91 men each; total, 1,131.

Each regiment is to be composed of civil and mechanical engineers, electrical engineers, and practical electricians, mechanics, artisans, draughtsmen, and men familiar with all kinds of engineering work, capable of being rapidly converted into military engineers with proper training.

He pointed out that in the contemplated occupation of Cuba, the character of the country and the probability of siege operations against Havana make it obvious that an unusually large proportion of engineer troops will be required.

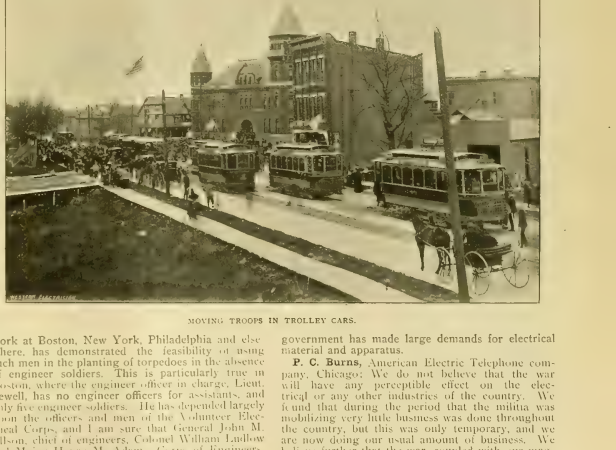
Modern warfare will involve the use of electricity in many ways. Movable electric generating plants will be used extensively both for both offensive and defensive night work, for lighting permanent camps, for the operation of pumps, hoists, drills, etc., in siege operations, and, in fact, under all conditions. Movable searchlight outfits will be in demand on the battlefield to search for the wounded, and Röntgen-ray outfits in field and permanent hospitals, and in many other ways not yet contemplated.

Photography will play an important part in reconnaissance work and no field topographical map will be regarded as complete without supplementary photographs showing the appearance of the ground occupied or to be occupied by troops, or over which projected movements are to be conducted.

Civil engineers capable of building and destroying bridges, tunnels, railway tracks, etc.; mechanical engineers, able to construct, operate, repair or destroy machines and mechanical appliances, such as locomotives, stationary engines, etc., and military engineers capable of laying out and constructing hasty entrenchments and field fortifications and carrying out the complicated work of siege operations will be in great demand.

The regular battalion of engineers of only 500 men, even it expanded to a war footing of 750 men, is entirely inadequate for such work, and, moreover, considerable numbers are now detached on torpedo work in connection with coast defenses.

Of the work already done Captain Griffin says: "The Volunteer Electrical Corps, raised from the employes of the electrical companies, which has been assisting the regular engineer officers in torpedo



MOVING TROOPS IN TROLLEY CARS.

work at Boston, New York, Philadelphia and elsewhere, has demonstrated the feasibility of using such men in the planting of torpedoes in the absence of engineer soldiers. This is particularly true in Boston, where the engineer officer in charge, Lieut. Sewell, has no engineer officers for assistants, and only five engineer soldiers. He has depended largely upon the officers and men of the Volunteer Electrical Corps, and I am sure that General John M. Wilson, chief of engineers, Colonel William Ludlow and Major Henry M. Adams, Corps of Engineers, and other officers familiar with the facts, will testify that the work done by the Volunteer Electrical Corps has been entirely satisfactory."

Detachments from the proposed Volunteer Brigade, it is pointed out, could, if it be deemed best, relieve nearly all of the regular engineer soldiers and many of the engineer officers from their present torpedo duty, and leave the regular battalion of Engineers free for service with the rest of the regular army. Such detachments are also capable of installing and maintaining all electrical appliances used in connection with coast defenses.

Moving Troops in Trolley Cars.—Reports from all parts of the country tell that the trolley has played the movement of the regular army and the national guard to their camps, aiding materially in the quickness of the movements. The correspondent of the Western Electrician at Niagara Falls furnishes the photograph from which the accompanying picture was made, and relates the following narrative: "In Niagara Falls Superintendent John C. Brewster, of the Niagara Falls and Suspension Bridge Street Railway company, placed the facilities of his line at the disposal of the Forty-second Separate Company in order that the company might go to the north end of the city and march to the south end, thus giving all the people an opportunity to see the company on its departure for the camp at Hempstead Plains, L. I. The illustration shows the crew in

[Continued on page 287.]

WAR OPINIONS.

S. D. Greene, General Electric company, Schenectady, N. Y.: It seems to me that the present war must necessarily check new electrical enterprises (where capital is to be raised) just as it will check new enterprises in other fields. Apart from this, it seems to me that the ordinary business of existing companies for light or power will continue very much the same as at present, although there will probably be a general inclination among consumers of light and power to economize in this as well as in other directions. The government will undoubtedly make large demands for electrical apparatus for military purposes, but such business is necessarily a small fraction of the total business of the country. We all unite, I fancy, in hoping that the war may be of short duration, and I think it is the duty of all good citizens of the country to do what they can to bring this conflict to the earliest possible close and with the greatest possible credit to the country.

E. H. McFall, National Automatic Fire-alarm company of Louisiana, New Orleans: As to the probable effect of war on the electrical industries of this country, we can only judge from present indications, which go to show that the electrical industries of the country will not suffer in the least from the Spanish-American trouble. Should there be an early termination of the war, which the present conditions indicate, I believe that the electrical industries will be benefited, owing to the fact that the government has made large demands for electrical material and apparatus.

P. C. Burns, American Electric Telephone company, Chicago: We do not believe that the war will have any perceptible effect on the electrical or any other industries of the country. We found that during the period that the militia was mobilizing very little business was done throughout the country, but this was only temporary, and we are now doing our usual amount of business. We believe further that the war, coupled with our magnificent victories, will advertise our country in foreign markets, with the result that foreign markets will be opened up for all lines of American goods.

F. W. Ferguson, Walker company, Cleveland: It is an admitted fact that national disturbances reflect directly upon general business conditions, and capital, which is always sensitive, is particularly so in times of hostilities. Therefore it would appear that new electrical street railway enterprises may be temporarily curtailed or postponed; but the demand for indispensable requirements necessary to meet the summer traffic and the development in electric lighting and power plants is exceptionally large and not likely to be seriously interrupted except by a war of long duration. But even in that event the resources of the United States are so diversified and comprehensive that I do not anticipate any material setback to the steady progress which is being made in the electrical business. Our plant factory and bound-ary so well equipped for the manufacture of large machinery and mammoth castings that we are at present running night and day on special work, exclusive of our electrical business. The United States government has taken advantage of our extensive facilities by awarding the Walker company urgency orders for a large number of disappearing gun carriages, to be used for coast defenses, and this work may necessitate considerable improvements and additions to our factory.

[Continued on page 286.]

DEVELOPMENT OF THE TELEPHONE FIELD.

Intermediate Switchboards for Series Toll Lines.

By H. P. Clausen.

Whenever two or more toll-line circuits meet at a centrally located point, the necessity arises for providing means for interconnecting the different branches; in other words, a toll switchboard must be installed. Viewed from a technical point, it is a simple proposition to supply the proper switching appliances for interconnecting toll lines; practically, however, it is found that most toll switchboards must necessarily be operated by inexperienced people, who are apt to create confusion and much loss of time

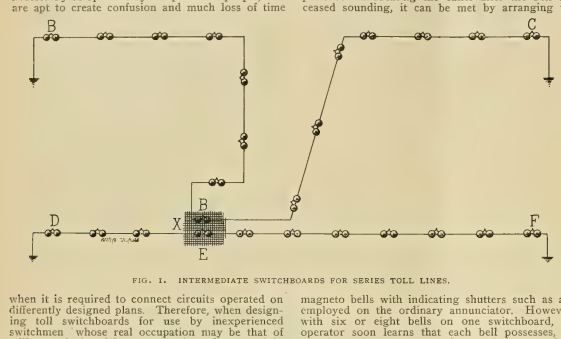


FIG. 1. INTERMEDIATE SWITCHBOARDS FOR SERIES TOLL LINES.

when it is required to connect circuits operated on differently designed plans. Therefore, when designing toll switchboards for use by inexperienced switchmen whose real occupation may be that of selling agricultural instruments drop theory and in its place employ sound judgment gained by a critical observation of apparatus that is being operated under adverse conditions.

Let us consider as the first case in hand conditions illustrated in Fig. 1. The circuit A B C contains 15 telephones connected in series; the telephone B located in the town X serving as a means of communication to the outlying stations; the telephone E, which is also located in X, serves in a similar capacity for the telephones connecting to the D E F line.

Quite often and mainly on account of the difficulties improperly designed switching apparatus might introduce if placed at the junction point X, an oral repetition of messages is preferred; thus when a subscriber at some station on the line A desires to communicate with anyone on the line D, the operator at the junction point X is requested to repeat the message. In Fig. 2 a method is shown that may be employed with marked success. The diagram re-

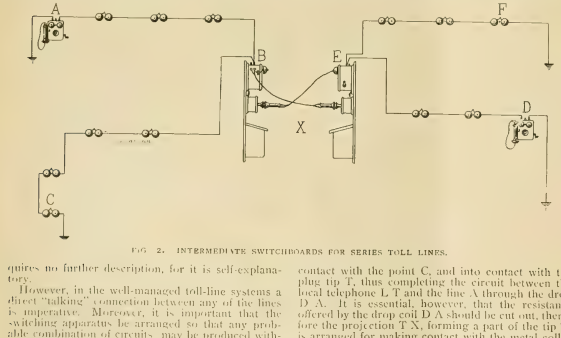

FIG. 2. INTERMEDIATE SWITCHBOARDS FOR SERIES TOLL LINES.

quires no further description, for it is self-explanatory.

However, in the well-managed toll-line systems a direct "talking" connection between any of the lines is imperative. Moreover, it is important that the switching apparatus be arranged so that any probable combination of circuits may be produced without creating any mutual interference. Another and equally important requirement is that the toll switchboard must be designed so that it is practically impossible to "hang up" any toll line circuit and produce at the switchboard a condition in the circuits which will prevent the recalling of a call originated at any of the outlying toll-stations. Fig. 4 represents the circuits of a toll switchboard designed for accommodating series-connected telephones employing the earth or a common wire as the return circuit. For the sake of clearness only two drops and jacks are shown. The line A connecting to D A and J A, and the line B to D B and J B.

Although we have shown the ordinary annunciator drop serving as the signal receiver, it is generally advisable to install instead a magneto bell, for, when a number of telephones are connected in one circuit, a system of code signaling becomes a necessity, and unless the operator at the switchboard is in constant attendance a code signal, though intended for someone on the same circuit, would be the cause of many useless trips, as the drop would indicate a call on the passage of the first impulse of current, thus calling for immediate attention, whereas the bell signal would only call the operator when sounding the local code. Regarding the difficulty experienced in locating the caller after the bell has ceased sounding, it can be met by arranging the magneto bells with indicating shutters such as are employed on the ordinary annunciator. However, with six or eight bells on one switchboard, an operator soon learns that each bell possesses, or may be made to possess a characteristic tone of its own; moreover, it is an easy matter to locate the caller, even if it is necessary to plug into several jacks until the proper one is found, for, in making a toll connection, the speed is not so large a factor as the certainty of its being properly executed.

Referring to Fig. 3, let us see what operations it is necessary to perform when telephone A desires to be put into communication with telephone B. Transmitting the call in a prearranged manner, it may be received at the switching station, either causing the falling of a shutter and closing a local bell circuit, or by sounding a prearranged code signal on a magneto bell. The switching station, it will be observed, is equipped with a regular telephone instrument. One of the line binding posts is connected to the earth wire and the remaining binding post is connected to a single conductor cord that has connected to its opposite end a single contact (common return) plug O P, which is so constructed that upon inserting it into the jack J A, the spring C C is forced out of contact with the point C, and into contact with the plug tip T, thus completing the circuit between the local telephone L T and the line A through the drop D A. It is essential, however, that the resistance offered by the drop coil D A should be cut out, therefore the projection T X, forming a part of the tip T, is arranged for making contact with the metal collar S, which when effected shunts the resistance out of circuit by reason of the collar S being connected to the line side of the drop coil. Therefore when either calling or talking over any circuit the operator has a direct connection to the line wire.

The operator, on being requested to produce a conversational connection between the A and B lines, inserts the operating plug O P into the line jack J B, and on finding the B line clear, at once proceeds to transmit the proper code signal for the desired station; on receiving a response, the C P connecting plug may be inserted into the jack J A, and after withdrawing the operator's plug from the jack J B the A P plug is inserted into the jack, thus establishing a through connection for the A and B lines. On closer examination it will be noticed that the C P plug is an exact duplicate of the operating plug, with the addition of a metal socket piece P S, which is in reality an extension of the tip T. The corresponding A P plug is also equipped with the tip T, and the socket piece P S, but the tip projection T X is not in an electrical contact with the plug tip T; in fact, the projection is merely an extension of the hard-rubber sleeve covering the larger body of the plug. As was described before, the metal projection T X serves as a means of shunting out the drop coil; therefore it is obvious that the drop coil must remain in the connecting circuit and operate as a clearing-out drop, whenever the A P plug is placed into a corresponding jack; whereas, the C P plug, wherever inserted, always shunts a coil out of circuit. Whenever the operator desires to listen to a conversation passing over the C P and A P plug circuit, it is only necessary to touch the socket piece F S with the tip of the operating plug O P. Listening buttons might be arranged and the listening-in would become more convenient, but considering the circumstances there is no valid reason for providing them, and therefore they should not be supplied.

The series connected toll-line system is liable to many interferences, but one of the most exasperating conditions is that which may be produced by the careless operator of some outlying toll station "hanging up" an entire circuit by allowing it to remain open at the switchboard. Referring to Fig. 3, it will be seen that the C P and A P plugs when in normal position allow the metal socket piece P S to rest in a seat provided in the plug supports C S and A S, thus completing the connection with the earth through a low-wound annunciation bell B B. Now, in case either the C P or A P plug is accidentally left in one of the line jacks, the conditions are not materially changed, for the magneto bell E B always presents an easy path to the earth for an incoming call, even if the drop coil D A has been shunted out of circuit as by the C P plug. If the plug O P belonging to the operator's telephone be left in one of the jacks, the telephone bell would naturally act as the receiver for that particular line.

As stated before, it is an easy matter to design a switchboard for interconnecting series toll lines, but when the designer is obliged to exercise an extreme degree of economy, and at the same time produce apparatus than can be understood by the most inexperienced manager, the problem assumes a more difficult aspect, for every additional connection, appliance or piece of apparatus tends to confuse the mind, and, though perhaps the arrangement produced may not be theoretically correct, it is the practical feature which is the most desirable.

Telephone Legislation.

Restrictions of telephone business are proposed by the anti-Bell forces in Maryland.

Two bills have been introduced in the Legislature regulating rates for service. One prohibits telephone companies from charging more than $5 per month for a telephone located within a radius of three miles from the central exchange, and $1 additional per month for every extra mile. When two or more telephones are rented on the same subscriber, not more than $4 shall be charged for each. The second bill repeals the act of 1894, which permitted a telephone company to make special contracts with subscribers. At present the Bell company evades the law which compels a like charge for a grounded circuit by using a metallic circuit and increasing the rates.

The act of 1892, under which the Bell company operated, provided that rentals for local service should be limited to $6.50 a month or $78 a year, and in 1894 the Chesapeake and Potomac Telephone company secured from the Legislature permission to make special contracts with customers for their benefit. Thereupon the company construed the amendment to mean that for $78 a year only the grounded circuit should be given. For an ordinarily good telephone of the metallic circuit the company put the price at $125 a year, and everybody who wanted a satisfactory service had to take it. It is this condition that has made possible the present crusade against the Bell interests in Maryland. It is believed as a result of the agitation that the "special-contract" feature will be abolished and that reasonable rates for first-class service will be established by law.

COMMUNICATION.

Auxiliary Telephone Signals.

To the Editor of the Western Electrician:

In the article which was published in the Western Electrician, April 30th, on "Auxiliary Signals as Applied to the Telephone," Fig. 11 should be made to read Fig. 12, and vice versa, and the switch S in Fig. 5 should have been connected as the switch S shown in Fig. 6, thus conforming with the description "the switch S connected across the extension bell terminals."

H. P. CLAUSEN.

Chicago, May 11, 1898.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

J. T. Davis has sold his stock in the Perry Telephone company of Perry, Iowa, to H. L. Thomas, and Edmund Nichols has sold his to John R. Swearingen. The company has completed its new line to Guthrie Center.

The Greene and Western Telephone company has been incorporated at Greene, Iowa, with $2,000 capital stock.

The Central Telephone company claims to have secured 400 subscribers in Oskaloosa, Iowa, and is doing well in Pella, Iowa, and other towns along the line of the proposed toll line from Des Moines to Ottumwa.

The Southern Dakota Telephone company is working to establish its lines in Mitchell, S. D., Chamberlain and other points.

Frank Lashway, telephone manager at Chippewa Falls, Wis., for the Wisconsin Telephone company, was married at Appleton, Wis., to Miss Allie Waldo.

The Hastings Telephone company of Hastings, Minn., has received materials and instruments for completing its system and will soon be ready for business.

The Elgin Telephone company of Elgin, Minn., is extending a line to Corra and may go west of there.

The Blue Earth Valley Telephone company will put in a new 200-drop switchboard and move its exchange at Blue Earth City, Minn. The changes will cost about $1,500.

The council of Thorp, Wis., is considering a franchise for the Wisconsin Telephone company.

Byron F. Fahnestock, manager of the Northwestern Telephone Exchange company's St. Cloud, Minn., office, has been transferred to Minneapolis. He is succeeded by C. H. Edwards, formerly manager of the Minneapolis branch office.

The Dwelle Telephone company of Lake City, Minn., expects to put in a metallic circuit from Lake City to Wabasha, Minn., as soon as possible.

The Minnesota Central Telephone company has arranged to extend its wires to Browns Valley, Minn.

The Northwestern Telephone Exchange company attempted to set poles on Lake street in Minneapolis recently. The city engineer had granted a permit, which was revoked afterward on account of the protests of property owners. The company went ahead and there was an exciting though bloodless contest until a sufficient force of police arrived to stop the work. The foremen of the gangs were arrested. The company holds that the city engineer has no right to revoke the permit after expense has been incurred.

Australian Telephone Statistics.

T. Howard, honorary secretary of the Telegraph Electrical Society of Melbourne, thus rebukes the London Electrician for copying from Electrical Engineering of Chicago an incorrect statement of the number of telephones in service in Australia:

"The number of telephones in use in Australia is given as 2,000, and as New Zealand is not mentioned in the list it may be assumed that that colony is included in the Australian total. From official returns at the beginning of 1897, the following telephones were in use in the various colonies, viz.:

"Tasmania and South Australia: Subscribers to exchanges 685 and 1,099 respectively.

"Western Australia: Exchange subscribers 942, private lines and extension telephones 157.

"New South Wales: Subscribers to exchanges (city, suburban and country) 3,991, extension lines 678, private lines 4[illegible]6, extra instruments in use 354, total 5,459.

"Victoria (end of 1897): Subscribers to exchanges (city, suburban and country) 3,088, private lines 185 (tenants in large buildings where sub-exchanges exist are not counted as subscribers); total telephones in use 5,000.

"New Zealand: Number of subscribers or connections March 31, 1896, 5,143; March 31, 1897, 5,747.

"So that the grand total of the whole of the Australasian colonies is 19,089.

"It must be remembered that this does not represent the telephones in use up to date. During the last year, owing to reductions in charges, there was an increase of over 2,000 subscribers in New South Wales alone, the number of telephones in use there in February, 1898, being 7,800. Allowing a proportionate increase on previous figures for the other colonies, it can fairly be stated that the total number of telephones in use in Australasia at present will be nearly 25,000, and not 2,000, as mentioned in the statistics of your contemporary."

Telephony in England.

In striking contrast to the complaints that have recently been published against the National Telephone company of England is the statement of the general manager of the corporation, William E. L. Gaine, at the annual dinner of the staff which was held in London last month. In the course of his address, he said:

"We have opened no less than 90 new exchanges; we have increased our clientele by upwards of 12,000 subscribers, after allowing, for those who from one cause or another cease to be subscribers, and we have now in this country nearly 800 exchanges in working order. Happily the great municipalities have recognized the enormous commercial advantages of the telephone as a means of communication, and have recognized that it is advisable in the public interest to make arrangements with the company which is charged, as the agent of the state, with the provision at the present time of this service, and the consequence has been that during the last year we have been able to make great strides in all the great English towns towards placing our wires underground and in bringing our plant—or doing something towards bringing it—into the most efficient condition for giving a service such as we know we can give, and such as the public has a right to demand. Now, with these facts before us, and knowing, as we know, the difficulties which have to be overcome, it is somewhat hard to find that the charge meets with acceptance, more or less, that the service rendered by this company is not an efficient service. I deny that entirely. I say that where facilities have been afforded, where we have had the opportunity of showing what we can do, the service of the National Telephone company will bear comparison with any telephone service in the world. It is said that figures cannot err, but they often lead people who use them to err very materially. Now an inefficient service which has conveyed about 430,000,000 effective messages surely cannot be truly said to be bad, particularly when this figure is compared with the number of messages in a corresponding service—that which is rendered by her majesty's government in the matter of telegraphs—73,000,000. I do not know that the telegraph service is inefficient, but there are the figures 73,000,000 telegrams by the State Department, whereas the National Telephone company is sending 430,000,000 telephone messages per annum.

"I took the trouble a little while ago to make inquiries about the telephone business of some other countries, because we hear a good deal about other countries in this connection. Germany strikes me as being not an unimportant quarter of the globe, and what are the facts there? Germany has a population of about 52,000,000, and is, we are told, well telephoned—cheaply and well telephoned. In Germany, with 52,000,000 of population, there are 107,000 subscribers' lines. In England, which is inefficiently and, I think they say, inadequately telephoned, with a population of 38,000,000 to 39,000,000, we have 106,000 subscribers' lines—not such a bad comparison. So that for every 300 of the population in Great Britain you have a telephone subscriber, and in Germany one for every 400. France considers itself one of the great powers; and in France, with a population which is, for comparative purposes, simlar to our own (39,000,000), there are not more than 30,000 subscribers; that is to say, one for every 300 of the population here, one for every 1,200 in France. Austria is a great country, but there you have only one subscriber to every 1,500 of the population. In Belgium there is one subscriber to every 680 of the population, and in Holland one to every 1,000. In view of these figures, and knowing what we are doing, what the enormous vitality of this business is, and its constant increase, and then to say that this country is inefficiently telephoned is nonsense, and we know it to be nonsense."

Another speaker, Lord Harris, complained of the number and nature of the "official inquiries" that had been held recently and of the attitude of those conducting them toward the corporation. He believed that many of the complaints against the service were unjust and without good cause. A case in point is cited as follows: "If any one of us sees a friend on the other side of the street talking with somebody else, and we want to speak to him, we have to wait until he has finished his conversation with the person with whom he is speaking, and yet the public—the uninstructed public—expect to get immediate connection with the person they want to talk to through the telephone, and complain if they get the response 'engaged' from the operator. Is that, after all, very remarkable? We know, as a matter of every-day experience, that we cannot get face-to-face conversations with our friends exactly when we wish. Is it, then, strange that it frequently happens when we want to talk over the wires, that they are engaged?"

Other speakers followed in similar strain, some as representatives of the company and others as subscribers, and all agreed that the service was highly efficient and satisfactory.

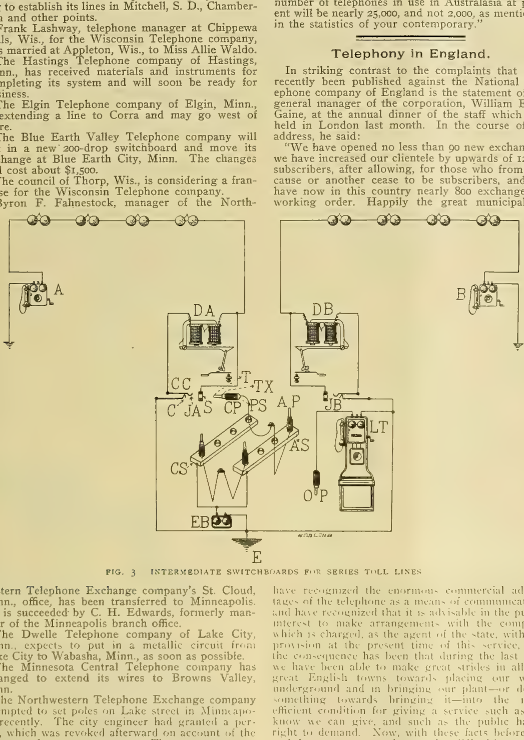

FIG. 3 INTERMEDIATE SWITCHBOARDS FOR SERIES TOLL LINES

Extensions and Improvements.

Buffalo aldermen have declined to grant franchises to two applicants for telephone rights.

The Pacific Telephone and Telegraph company of San Francisco is removing its overhead wires and poles. A subway system is being installed.

Chattanooga, Tenn., is considering the question of granting a franchise to a new telephone company, as the high rates of the East Tennessee company cause much complaint.

A telephone exchange will be established at Durand, Mich., a franchise having been granted by the council. The exchange will be in operation by August 1st, and the rates will be $20 for business houses and $15 for residences.

Clergymen enjoy telephone service free in Monroe, La., where the Cumberland Telephone and Telegraph company is engaged in a rate war with the new Monroe Telephone company, resulting in a reduction in cost to 50 cents a month.

The Missouri and Kansas Telephone company has decided to construct a line from Pittsburg to Chanute. The company will also build a line from Joplin to Springfield, Mo. It is intended to construct a network of telephone lines in Kansas and Missouri.

The Delaware County Telephone company of Chester, Pa., has decided to extend its lines to all important points in the county during the present year. The company will probably increase its capital stock from $25,000 to $75,000.

At the annual meeting of the Oriental Telephone and Electric Light company, which was held in London recently, the chairman called attention to the fact that the net profits exceeded those of the previous year by £1,000. The expenditure had been increased by the removal of the exchange to a more central position and providing a new switchboard. The rate of exchange had been more favorable than it had been for the last seven years. Business all round had been making steady progress and the outlook was exceedingly promising, he said.

George W. Schening of Memphis, Tenn., has sold his telephone exchange at Corinth, Miss., to the Cumberland Telegraph and Telephone company. This system consisted of 100 telephones and a 150 number switchboard. The Cumberland company has also purchased the telephone exchange at Winona, Miss., which has been operated for about two years. Mr. Harvey had 50 instruments connected to a 60 number switchboard. Since the Cumberland Telegraph and Telephone company purchased the Southern Bell telephone interests, it has been making great improvements, and is now rapidly extending the long-distance service south, east and west from Memphis. At present the lines extend about 100 miles south, where they branch off, going under the Mississippi River at Helena, Ark., and west along the Iron Mountain branch of the Southern Pacific railway. The company will soon open offices at Pine Bluff and Little Rock, Ark. The new manager of the Cumberland company, Leland Hume, is introducing many improvements in the service.

WAR NEWS.

[*Continued from page 283.*]

front of the armory on Main street, on the afternoon of Sunday, May 1st, the company having boarded the two cars seen in the distance, while those in front of the armory and in waiting are being filled by veterans of the late war and veterans of the company. The parade at the Falls was very notable from the fact that two companies of firemen from Niagara Falls, Ont., crossed the steel arch bridge and, headed by the Union Jack and a Canadian band, took part in the demonstrations of the day. The appearance of the British flag in the line created intense enthusiasm. It is probable that such an exhibition of friendship was never before shown as that of the flag of a neutral country floating in line with troops of another country who were departing for the scene of battle. The feeling of the Canadians was increased by the fact that Fred C. Newman, one of the marines lost on the ill-fated Maine, was a member of one of the Canadian fire companies, and his brother carried the British flag in the parade. The charge of the Canadians to the departing troops was, "Remember the Maine, and we'll remember you." The incident will attest the friendship that exists between the two peoples of the Niagara border, and still closer cements the ties.

The Manila-Hongkong Cable.—It appears that the cutting of the cable which connects Manila with Hongkong and the rest of the world was done by Admiral Dewey. The American commander regarded this action as necessary because the Spaniards had control of the land end of the cable and could avail themselves of this means of communicating with Madrid pending the surrender of Manila. As the admiral had not a sufficient landing force to capture the cable office, he decided to cut the cable, so that the enemy might have no advantage over him in telegraphic communication. It is reported that he sent word to the governor by the British consul that if he was presumed to send his dispatches to the United States government the cable would not be cut. The governor refused to promise, and Admiral Dewey decided to stop all communication between Manila and Madrid. The cable was cut on Monday, May 2d, the day after the battle.

In relation to the break in the service the manager of the Western Union office at New York gave an interesting interview to a reporter of the New York Sun: "We received no notice," he said, "of the nature of the interruption, of its cause, or of its probable duration. All notices of breaks in cable service come to us from Berne, Switzerland. At Berne is the Bureau International des Administrations Télégraphiques. This bureau is the center of all the government telegraph systems all over the world. There they meet in conference. There are between 40 and 50 governments which control their telegraphs as the United States does its mails. These form the 'signatory powers,' as they are called. The various privately controlled systems, perhaps between 15 and 20 in all, are admitted by courtesy to the conference held at Berne. So all notify Berne of any interruption in the service of their systems. Berne sends notices to every system, which in turn notifies its own offices. Yesterday the Eastern Extension system, which is under the same control as the Eastern company, notified Berne of the interruption between Hongkong and the Philippines. As to repairing such a break, if the weather is favorable and the repair ship is on the spot, connections can be made in an hour. But I do not know where that system has its ships at present, and it may take two weeks to get them to Manila. Hongkong is the nearest point to Manila that we can reach, and Labuan in Borneo the next nearest. We have had no interruptions in cable connections with Cuba or Porto Rico except in the way of censorship."

Some discussion has arisen as to the legal aspects of Admiral Dewey's act. It is generally held that all nations reserve to themselves the right to cut submarine cables in wartime as a military necessity or belligerent right, but it is possible that a civil claim for damages to the service may be admitted.

Foreign Telegraphers Dismissed.—At the request of Lieutenant Maxfield, U. S. A., the government ordered all the foreign employes in the offices of the United States and Hayti Cable company in New York have been "laid off" from the company's service, their places being filled by native-born American citizens. This action is only preliminary to the suspicion of bad faith or treachery attached to any of the persons who have been discharged. It is also said that secret service men have been detailed to duty in the cable company's office to watch all persons who may offer for transmission dispatches suspiciously worded or written in cipher.

Value of Searchlights.—If the Spanish fortifications at the entrance to Manila Bay had been provided with electric searchlight the American fleet would not have passed them as easily as it did at night, securing an advantageous position to attack the Spanish fleet at dawn. John McCutcheon tells the story in his graphic account of the battle cabled to the Chicago Record from Hongkong: "Only the signal lights absolutely necessary were shown after leaving Subig Bay, and before the attempt was made to run past the forts of Corregidor all lights were ordered extinguished. As the ships approached the south channel entrance to the harbor they slowed up. Each ship carried a single stern light that would not have been visible from the shore under any circumstances. The McCulloch being at the rear of the line, we who stood on her deck could mark the formation of the fleet by the dim waver of small lights moving ahead of us. We could see no lights ashore and were relieved to find that the enemy had no searchlights. It was a good night for running past the forts. There was a moon, but the sky was full of shifting clouds which covered it at times. It is probable that the darkened vessels could not have been seen by anyone watching from either shore. The south channel is five miles wide, and it is said to be at least 200 feet deep."

This instance shows the real value of searchlights in night attacks on harbor defenses. The lesson should be borne in mind by our own fleet at home abroad, if there are places open to attack still unprovided. It is to be noted that the government has completed arrangements for borrowing the electric searchlight at Mount Love, in California. It will be used at night to sweep San Francisco Bay and the Golden Gate. This searchlight was at the time of its construction one of the largest in the world. It was used at the World's Fair at Chicago.

The Signal Service.—Probably the largest and best-equipped balloon signal corps ever gathered together by the United States will accompany the troops to Cuba. This corps of wig-waggers will have everything which the science of military communication has invented and brought into use. Reels of telegraph wire, containing enough to run a line from Matanzas to Havana, and insulated so that it can lie on the ground if lack of poles, trees or fences prevent stringing the wire overhead, will be taken by the troops, the constructing party going with the invading forces stringing the line as the troops move forward.

On a flat car at Tampa is a military balloon large enough to carry two men. This balloon, says Malcolm McDowell in the Chicago Record, with its wagon train, steel flasks in which 200 cubic feet of hydrogen gas is compressed into one cubic foot, and a drum and reel for the rope which holds the balloon captive to the signal men are transmitting messages by flags or electric searchlights, or are making observations and drawing a map for the commanding officer. Lieut. Maxfield of the signal corps will have charge of the balloon, which will be 90 feet in cubic feet in size. The hydrogen gas is compressed into seamless steel flasks, the dimensions of each flask being one cubic foot. Into a flask 200 cubic feet of hydrogen gas is forced by powerful compressors stationed at the base of operations. The wagons of the balloon train will carry a number of these charged flasks. When it is intended to use the balloon 150 of the flasks will be used in inflating the balloon.

Capt. Robert E. Thompson, the first censor which the government placed over newspaper men in the Key West cable office, is the inventor of a unique bicycle to be used in laying a temporary telephone line. A reel on the bicycle contains several miles of two insulated copper wires. A corresponding office desiring to talk with another officer on the field sends the signal man on his bicycle. As the bicycle moves over the ground the wire is reeled off. At the end of the run the signal man dismounts, salutes and presents the telephone to the officer. He "rings up" the commanding officer, talks with him, hands the telephone back to the signal man, who at once retraces his track, the reel automatically taking up the wire.

Capt. Theodore Kane, U. S. N., in charge of the coast signal service of the Atlantic division, has established his headquarters on board the naval reserve ship New Hampshire. His assistant is Lieut. Lucas, formerly of the naval reserve, but now of the regular navy. Four signal stations are now manned by the men of the First Battalion, namely, at Montauk Point, Quogue, Fire Island and Cape Henlopen. At each station are detailed a quartermaster and four men. Eight telegraphers of the newly enlisted First Separate Division have been detailed for work at these stations and at Washington. In addition, there are 12 operators of the new division under Capt. Kane on the New Hampshire.

Adjt. Gen. Barrett has sent from San Francisco to Gen. Greely, chief of the Signal Corps at Washington, information that 100 men of California's signal corps are fully equipped and will be ready to go to the front immediately. The naval militia is urging the representatives of the state in Washington to help them get into action. They are extremely anxious for active service and duty.

Gen. Greely says that the telegraphic signal system is now complete for the entire Atlantic coast north of Fort Caswell, North Carolina, and the important defenses—particularly those at Boston, New York, Delaware and Chesapeake bays—are in close communication with each other and with Washington.

The Senate has passed the bill authorizing the enlistment of a number of signal corps. The corps shall consist of one colonel, one lieutenant-colonel, one major as disbursing officer, and such other officers and men as may be required, not exceeding one major for each army corps and two captains, two first lieutenants, two second lieutenants, five first sergeants, 10 sergeants, 10 corporals and 30 privates to each organized division of troops. Two-thirds of all officers below the rank of major and a like proportion of the enlisted men shall be skilled electricians or telegraph operators.

Captain William J. Lloyd, assistant district superintendent of the Western Union Telegraph company at Chicago, has resigned from the Signal Corps of the Illinois National Guard. John W. McConnell has been detailed to act as captain and will receive his commission, it is said, in a few days from Governor Tanner. Capt. Lloyd has taken great interest in the Signal Corps, and his skill and popularity have been of much value to the service.

Miscellaneous Notes.—A Cleveland dispatch states that Norman Harrington, the American engineer who faced the Spanish mob in Barcelona with the American consul, is a graduate of the Cleveland public schools and Case School of Applied Science in that city. He has many relatives and friends there, but his wife and children live in Chicago.

The Commercial Cable company sends out notice that the cable between Montevideo and Rio Grande do Sul is interrupted. This cuts off telegraphic communication with Montevideo and places south, including Buenos Ayres. The same company announces that it is advised that telegrams for Spain written in code or cipher will be accepted only at sender's risk.

The Tompkinsville lighthouse station on the Atlantic coast is now connected by telephone with the stations at Navesink, Montauk Point and Block Island. Connections will also be made with Fire Island. Orders have been issued to make telephone connections between all important lighthouse stations.

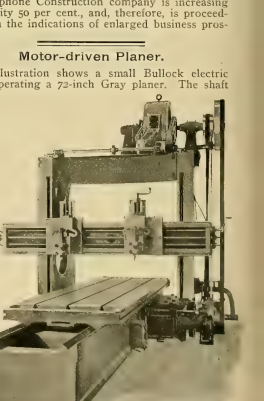
WAR OPINIONS.

[*Continued from page 283.*]

J. E. Keelyn, Western Telephone Construction company, Chicago: My belief is that the war will be of short duration. The large expenditures necessary will have a stimulating effect upon trade which will be more felt later on. The depressing effect upon stocks and financial institutions will not suffice to interfere very greatly, although concerns doing business upon borrowed capital will be in a weakened position. The electrical trade has passed through a period of depression and injudicious competition, resulting in an experience that warrants reasonable hope of a gradual improvement, even under war conditions, and a tremendous development under favorable conditions without war. The Western Telephone Construction company is increasing its capacity 50 per cent., and, therefore, is proceeding upon the indications of enlarged business prospects.

Motor-driven Planer.

The illustration shows a small Bullock electric motor operating a 72-inch Gray planer. The shaft



MOTOR-DRIVEN PLANER.

of the motor is coupled direct to the main driving shaft of the planer. The motor is placed on top of the tool allowing a traveling crane to pass over it. It is shunt wound to give constant speed under varying loads and has a capacity of 12 horse power. The Bullock Electric Manufacturing company devotes especial attention to the electrical driving of machine tools.

Electrical Incorporations.

Electric Street Railway company, Bloomington, Ill., to build a street railway; capital stock, $20,000; incorporators, W. H. Beaver, J. W. Gray and J. Y. Chisholm.

Desplaines Valley Electric Railway company, to construct a railroad from some point in the township of Lyons to some point in Chicago; capital stock, $100,000; incorporators and first board of directors, Nelson F. Merrill, Hiram A. Johnson and H. Wallace Percell of Chicago, Henry B. Fargo of Geneva and Samuel S. Garman, Jr., of Oak Park.

Regulation of Compound-wound Dynamos.

[*Continued from page 281.*]

The claims of the Brush patent are as follows:

1. In a dynamo-electric machine, the wire or helix E, having a comparatively high resistance and kept constantly in closed circuit while the machine is running, in combination with the magnet wire or helix F, as commonly employed.

2. In a dynamo-electric machine in which the coils around the field-of-force electro-magnets are included in the main or operative circuits, the combination of such main circuit with a constantly closed differential circuit of prescribed resistance, for the purpose of maintaining the flow of the current through the coils surrounding the electro-magnets in the machine when the main or operative (external) circuit is broken, substantially as shewn.

The Brush dynamo was intended for use in electroplating devices. A number of machines were built under the Brush patent and were successfully operated long prior to the date of the Edison application. Some of these are operative machines at the present time. Two of them are in evidence.

The defenses are lack of novelty and invention, and non-infringement. The principal defense is lack of novelty, and it is based upon the Brush patent just quoted.

The action was commenced December 23, 1893. It was argued February 8, 1898, and was finally submitted March 9, 1898. The record contains 2,454 printed pages and the briefs 800 printed pages.

Edmund Wetmore and Richard N. Dyer for complainant.

Henry A. Seymour, Robert S. Taylor, Charles A. Brown and Seward Davis for defendants.

Coxe, J.

Although this record has been expanded beyond reason and precedent, it will be noted that the real issue is one of the simplest that can arise in a patent cause, viz., whether the patent is invalidated by a single prior patent?

The best evidence of what the patent covers is the patent itself. It states that it is for "a new and useful improvement in regulating the generative capacity of dynamo-electric machines." The claims are for the dynamo in combination with translating devices in multiple arc; but as this arrangement of translators has been well known since 1875, invention cannot be predicated of this element of the combination; indeed there is no pretense that it can be. If invention can be found at all it must, therefore, be in the dynamo.

The object of the patentee was to produce means, assuming the translators to be lamps, by which the turning on and off of the lamps shall cause immediately a proper regulation of the current energizing the field magnet of the dynamo without the help of any other mechanism. In short, the dynamo was expected automatically to adjust its generative capacity. The translating devices shown in the drawings are lamps, but the claims are not limited to lamps and there is no canon of interpretation familiar to the court which will justify a construction so narrow. The claims do not speak of lamps. The words are "translating devices," and there can be no doubt that any translating devices arranged in multiple arc are within the claims, which unquestionably cover motors, plating baths, heaters and other similar devices.

The drawing shows a rudimentary dynamo of the conventional Edison type. It is the same dynamo which appears, mutatis mutandis, in a large number of patents which emanated about the same time from the Patent Office.

The dynamo of the drawing has compound windings, a vertical field magnet with pole pieces at the bottom and a field wound with two coils -a shunt coil of high resistance and a low-resistance coil in series with a lamp circuit. The shunt circuit may, if desired, be supplied from an external source. The main conductor is brought up on one side and wound around the magnet, afterward extending out parallel with the outer conductor of the exterior circuit.

The specification states that when translating devices are first put in circuit the magnet is sufficiently energized by the interior circuit, but as the number of translators is increased the resistance of the exerior circuit is lowered, and as they are thrown out of resistance of the main circuit increases and the energy of the magnet is lessened by the decrease of current in the main conductor. This is practically all there is of the specification. Considering the far-reaching, all absorbing claim which is now asserted for this patent, it must be admitted that the specification is most meager and unsatisfactory. It is almost a skeleton. If it were expressed in the full, clear and concise terms required by law, it is fair to presume that the expert witnesses, at least those on the same side of the controversy, would agree as to its scope and meaning. It will be observed that it says nothing about "constant potential," or, except inferentially, the means of securing constant potential. All details as to size of the field magnets, the relative size of the coarse and fine wire and the length and number of coils of fine wire are omitted, and yet it is maintained that sufficient information is conveyed to enable an electrician to construct the highly organized and efficient machines of the present.

The combination of the first claim contains the following elements:

1. A dynamo. 2. Translating devices arranged in multiple arc. 3. Field circuit of constant resistance for primarily energizing the field magnet. 4. Another field circuit whose resistance is varied by the addition and removal of translating devices.

The elements of the other claims are substantially similar, and in view of the conclusion reached it is unnecessary to consider them in detail. Claim 3 differs from the other two, in that the shunt circuit must be supplied from the main conductors.

It will be seen that the first claim is not for a dynamo of the Edison type or for the system of electric lighting adopted by him, but, on the contrary, that it is broad enough to cover, and does cover, any dynamo having the described characteristics in combination with any translators in multiple arc.

The Brush patent relied upon by the defendants was applied for 17 months before, and was granted one month before, the earliest date fixed for the alleged Edison invention.

The Brush patent is for an improvement in dynamo-electric machines and has for its object the maintenance in such machines of a magnetic field while the machine is running, whether the external circuit is closed or open.

Without analyzing the patent in detail, suffice it to say that the description is specific, carefully drawn and clearly illustrated by diagrams. The dynamo of the patent is a compound-wound dynamo having a shunt and series coil, the former of high resistance and the latter of low resistance. In some of the figures the series coil is wound over the shunt coil; in others the shunt is wound over the series, and in another figure the two coils are wound on opposite ends of the same core. The dynamo is designed to generate and maintain a sufficiently constant electromotive force and produce an amount of current always corresponding to the amount needed by the devices in the working circuit. Mr. Brush shows his machine in combination with electroplating in multiple arc, and Mr. Edison shows his in combination with electric lighting in multiple arc. This is the principal distinction between the two. If the one multiple-arc circuit be the equivalent of the other, then it cannot be denied that every element of the patent in suit is found singly and in analogous congeries in the Brush patent and that they are described there so as to be more readily understood, at least to the uneducated lay mind, than in the Edison patent.

Not only is this clear from the Brush patent, but the proof shows that a number of machines were built pursuant to its directions and were commercially used more than two years prior to the date of the application for the Edison patent. These machines exist at the present day, and what is quite remarkable and almost unique in patent litigation is the fact that, in an art which has progressed with giant strides, machines made nearly 20 years ago are not only operative, but practically as successful as when first built. Two of these working dynamos have been introduced in evidence, one by the complainant and one by the defendants. Each is capable of doing the same work now as in 1880. All of the Brush dynamos were originally used in electroplating devices. That a plating bath is a translating device, that the articles placed therein to be plated are connected in multiple arc and that such an arrangement is the equivalent of a multiple-arc lamp circuit, seems to be established by an overwhelming preponderance of evidence. Not only do the expert witnesses called for defendants testify to this, but so also does the principal expert witness for the complainant, whose vast fund of information regarding matters electrical is well known to this court. Not only so, but the proposition has received judicial sanction in the "Feeder case," where the Court of Appeals for the Third Circuit say:

> In the art of electroplating, as practiced long before 1880, we find an arrangement of circuits substantially the same as that of the patent in suit. Here a large number of articles to be plated simultaneously are suspended in the bath by separate wires attached to a metallic rod placed across the top of the tank, that is to say, the articles are arranged in multiple arc with respect to the electric current. Westinghouse v. Edison Co., 63 Fed. Rep., 588, 594.)

It must be conceded, therefore, that if the claims of the patent in hand are to be construed according to the plain letter of their meaning, without importing therein limitations and refinements not found in the patent, but suggested by subsequent and more accurate knowledge, the patent is invalidated by the patent to Brush and the machines made in accordance therewith.

But it is argued that the patent is for a peculiarly regulated compound-wound dynamo which secures constant, or nearly constant, potential in combination with incandescent lights arranged in multiple arc or other analogous devices requiring the same constant potential. In brief, that it is for the Edison dynamo in combination with the Edison system of electric distribution. It is maintained that the Edison patent discloses all this and the Brush patent does not disclose it.

Even though this position could be maintained, it is still a question whether it involved invention to secure more accurate regulation after the Brush patent had told the electrician how to secure regulation sufficiently perfect to be successful in the electroplating art. It would then seem to be a mere matter of winding within the knowledge of the skilled electrical engineer.

But a sufficient answer is that the courts are not permitted to construe a patent by reconstructing it to conform to what the court may think was in the mind of the patentee at the time.

Assuming that the dynamo shown in the Edison patent could be used for electroplating and was so used in place of the Brush dynamo, it would not have conveyed to the art any information for producing constant potential which was not conveyed by the Brush dynamo. Translating devices which require constant potential should be harnessed to a dynamo which produces constant potential, but it does not follow that because they are shown thus diagrammatically connected that the dynamo so described will secure constant potential or tell others how to secure it.

The Edison patent, as before stated, says nothing regarding constant potential and gives no information as to the means of securing it which is not found equally well stated in the prior patent. The claims are perfectly clear and intelligible, and there is no precedent for reading into them limitations not found in the patent. White v. Dunbar, 199 U. S., 47; McClaim v. Ortmayer, 141 U. S., 419; Home Co. v. Singer Co., 68 Fed. Rep., 224.

It is doubtful if Mr. Edison had in mind at the time he applied for the patent all of the improvements, perfections and refinements which are now asserted.

In 1879 the art of electric lighting was in its infancy. With the modesty which is usually found in men of genius, Mr. Edison frankly admits his lack of knowledge upon the subject now under discussion. He says: "As I knew nothing about dynamo machines, I tried to get information from electricians and books." His memory is also vague as to the success of the compound-wound dynamo. He recollects that there was a great deal of trouble with the machines; none of them worked; but he attributes their failure to variations in the speed of the engine that operated them.

Mr. Brush, on the other hand, thoroughly understood compound winding in connection with other devices in the art of electric lighting and had proceeded far in the successful construction of dynamos.

Were it important to inquire which of these two men would be most likely to produce a working machine having the necessary characteristics, there can be little doubt that Mr. Brush would be chosen. But such an inquiry seems irrelevant. The patent law cannot be administered along such lines as these. Patents are formal grants controlled by carefully drawn statutes and strict rules, and must be construed as other similar documents are construed. The court is not permitted to inquire what the patentee might have done or was capable of doing. The question is: What did he do? Conjecture and speculation are out of place in interpreting the claims of a patent. But even if the claims be limited to incandescent lamps in multiple arc circuit, it would seem that they are met by Brush dynamos. Several tests of these dynamos in connection with lamps were made, one of them being made at the argument.

The court makes no pretension to anything but a most superfical knowledge of this complex subject, which can hardly be mastered after the engrossing study of years, but it seemed to the court that the test demonstrated what the defendants sought to prove. The machine regulated automatically and maintained a constant electromotive force within permissible limits of variation. There was no noticeable variation in the lamps from no load to full load.

The other experiments described in the record appear to have been similar in character and to have had similar results. The court cannot resist the conclusion that the claims, construed as they must be construed, are invalidated by the Brush patent and the dynamos built thereunder. A Brush plating machine, if made now for the first time, would infringe these claims; being, in fact, made before, it anticipates them. But the learned counsel for the complainant insist:

> That even assuming the Brush plating dynamo to be a compound-wound dynamo within the scope of the Edison patent, there was, under all the circumstances shown by the record in this case, invention involved in the employment of such a dynamo in combination with a multiple-arc system of electrical distribution, on account of the discovery that such a dynamo, when the shunt and series coils were properly proportioned, would secure automatically the peculiar regulation to compensate for variations in the load which is required by such a system.

The doctrine of Potts and Creager, 155 U. S., 597, is invoked in aid of this contention.

As has frequently been pointed out, this case has created no new rule upon the question of double use. The case was peculiar upon the facts, which presented an entirely different condition of affairs from that developed in the case in hand. It has always been the law that invention must be denied to one who merely takes a device which has been used in the same or in an analogous art and uses it in new environments to accomplish a similar result. Stearns & Co. v. Russell, 85 Fed. Rep., 218, and cases cited.

It requires only the skill of the mechanic in the particular art to make the transfer from one branch thereof to another branch. An engineer who has used his engine to operate a series of looms knows enough to connect his driving wheel with a series of knitting machines, and a competent electrician who has used a dynamo successfully with one series of translating devices should be able to use it in connection with another series of translating devices. In other words, the character of the translating devices does not change the character of the dynamo, and an electrician does not become an inventor because he attaches a series of lamps to a dynamo which had been used in connection with a series of heaters.

The complainant's proposition, if sustained, would lead to the conclusion that Mr. Brush, after having obtained his patent in which the dynamo is described

as suitable for an electroplating circuit, could have attached the same dynamo to a well-known lamp circuit and have obtained another patent for that, and so on, as often as he changed the character of the translators.

Even though this work required enlargement, adjustment and some change in the winding, it would still be a question of degree within the realm of the skilled mechanic. An electrician would know how to adjust the machine to do the required work and adapt it to the new environment. An illustration is found in the record. Mr. Edison says that the first dynamo made by him did not work because of variation in the speed of the engine, occasioned by poor governing, "as a compound-wound machine should have a regular speed to utilize the invention; but after a while the demand for close regulation was met and engine builders were enabled to build engines that were very reliable and then the conditions for the employment of compound machines were met."

It will hardly be pretended that the engine builder who produced better regulation as the demands of the market required it was entitled to a patent. It would seem also that a skilled electrician would know how to adjust the Brush compound-wound dynamo to the new conditions of an incandescent-lamp circuit the moment the two were brought together. It would be like operating a carriage with a motor which had previously propelled a boat, or using a bullet-mold for making pills.

To restrict the Brush patent to electroplating would be as unfair as to restrict Edison to electric lighting. The one illustrates his dynamo in connection with the first-named translating devices, and the other with the second-named devices.

As before stated, the patent cannot be limited to any one multiple-arc system of electrical distribution, but if it could be, invention is not involved in changing one series of translating devices for another.

It seems probable that, if this controversy related to any other machine for generating and regulating power, contention would cease the moment a device was discovered in the prior art as near to the patented machine as Brush is to Edison. The mystery and uncertainty which surrounds everything relating to electricity arouse a feeling of admiration, almost akin to reverence, for those men who have subdued this unknown and dangerous force and made it do the world's work, makes the court diffident about applying those principles which are axiomatic in the patent law. It is always the apprehension that injustice may be done through failure to comprehend the abstruse and difficult problems presented. This fear has been augmented in the present instance and the difficulties of understanding the problems involved have been vastly increased by the record, into which has been dumped haphazard everything which either party believed had a bearing not only upon the point in issue, but upon the general subject of electrical distribution. But even were there more doubt as to the correctness of the conclusion reached, the court should still hesitate to enforce a patent in the sixteenth year of its age, and thus lay the entire art under tribute, when the public has had a right to assume that such a system as the defendants are using would not be molested.

The bill is dismissed.

Patent Office Rules Amended.

The commissioner of patents has promulgated the following amendments to the rules of practice of the Patent Office with the sanction of the secretary of the interior:

Rule 135. Upon the filing of the appeal the same shall submitted to the primary examiner, who, if he finds it to be regular in form, shall within five days from the filing thereof furnish the examiners-in-chief with a written statement of the grounds of his decision in all the points involved in the appeal, with copies of the rejected claims and the references applicable hereto. The examiner shall at the time of mailing or delivering said statement supply a copy of the same to the appellant. If the primary examiner shall decide that the appeal is not regular in form, a petition from such decision may be taken directly to the commissioner as provided in rule 145

Rule 145. [on] petition stating concisely and clearly any proper question which has been twice acted upon by the examiner, and which does not involve the merits of the invention claimed or the rejection of a claim, and also stating the facts involved and the point or points to be reviewed, an order will be made fixing a time for hearing such petition by the commissioner and directing the examiner to furnish a written statement of the grounds of his decision upon the matter averred in such petition within five days after being notified of the order fixing the time for hearing. The examiner shall at the time of making such statement forward a copy thereof to the petitioner. No fee is required for such a petition.

National Electric Light Association.

President Insull announces that all the arrangements for the meetings of the National Electric Light association have been completed, and that with one exception the assignments for papers have been accepted. It is proposed to have six set papers, and, in addition, a number of topical discussions. Thus far five papers have been arranged for, but President Insull has not yet received formal notice of acceptance of the invitation extended to prepare the sixth paper.

The programme thus far includes the following list of papers:

"Cost of Generation and Distribution of a Unit of Electricity." By Calvin W. Rice.

"General Distribution from Central Stations by Alternating Currents." By Herbert A. Wagner.

"General Distribution from Central Station by Direct Currents." By Louis A. Ferguson.

"Public Lighting with Relations to Public Ownership or Control." By Alex Dow.

"Transformer Economy." By Winder Elwell Goldsborough.

It is expected that the discussion of the question of direct and alternating systems will bring out the special advocates of each method, and this feature, therefore, is anticipated with keen interest by practical central-station men.

The Trunk Line association, Central Traffic association, New England Passenger association, Southern Passenger association and the Western Passenger association have granted a rate of a fare and one-third, on the certificate plan, from all points in their territory to Chicago and return, for delegates attending the twenty-first convention of the National Electric Light association, to be held June 7th, 8th and 9th. The convention hall and headquarters will be at the Auditorium Hotel. The rates are $3.50 to $8 per day on the American plan and $2 to $4 per day on the European plan, for each person.

National Electric Light Convention, Chicago, June 7th, 8th and 9th.

The most popular line from Cincinnati, Louisville and all points South to Chicago is the Big Four Route via Indianapolis; magnificent sleeping cars and unequaled dining-car service. For maps, rates, etc., address E. O. McCormick, passenger traffic manager, Big Four Route, Cincinnati, O.

CORRESPONDENCE.

New York Notes.

New York, May 9.—The great electrical exhibition is, of course, the main topic of interest among electrical men nowadays just at this time. It is truly a large and interesting display of electrical devices, from which the technical man can receive instruction and the casual visitor entertainment. The projectors of the show deserve the success which they seem likely to achieve.

It is said that the specifications for fitting the Forty-second street, Tenth-avenue and Boulevard surface lines with the underground electric system have been completed and that bids for the work will be advertised for within the next two weeks. It is expected that the change in the motive power of these roads will be complete by the fall. Mr. Lauterbach, the counsel for the Third Avenue company, says that probably within a year all the horse and cable lines operated by the Third Avenue company will be turned into underground trolley roads. The main line in Third avenue will, however, be the last to be so equipped. The company owns between 70 and 80 miles of tracks, and the cost of changing the power and providing new rolling stock will be at least $5,000,000. Work on the power house, which it is proposed to build at Kingsbridge road and Two-hundred-and-sixteenth street will be begun next month.

The Scientific Alliance, composed of the New York Academy of Sciences, the Torrey Botanical Club, the New York Microscopical Society, the Linnaean Society of New York, the American Mathematical Society, the New York Mineralogical Club, the New York Section of the American Chemical Society and the New York Entomological Society, is endeavoring to raise money to erect a building. Charles F. Cox is president of the Alliance and Prof. N. L. Britton is the secretary. It is the ambition of the active men in the movement to found an institution which should combine the objects of Burlington House, Piccadilly, London. Burlington House is the headquarters of the Royal Society, the most famous scientific organization of Great Britain, and contains interesting astronomical, antiquarian, chemical and geological relics. The Royal Institution includes chemical laboratories, provides other encouragement for original research in chemistry and physics and gives free lectures. It was here that Thomas Young, Humphrey Davy, Michael Faraday, John Tyndall, Lord Kelvin and Lord Rayleigh conducted their historic investigations. Plans have been prepared for the building proposed, which is to be 100 feet square and is intended to stand on a corner and occupy four city lots. It is proposed to let the upper stories or stores for purposes of revenue, which is to be increased by letting lecture halls occasionally. Thus, it is hoped, all of the running expenses of the institution will be met. The main portion will be designed to seat one thousand persons, and is reached through ample hallways from the street. On the second floor there are to be a large parlor or clubroom for social purposes and an assembly room for large meetings. The remaining space on this floor and all of the third and fourth floors will be devoted to laboratories and small rooms for the societies. It is proposed to have four of the former and twelve of the latter. The fifth floor would be occupied by the library and reading-rooms, and would easily accommodate 200,000 books. It is estimated that the land for this hall of science would cost not more than $300,000 and the edifice about $300,000.

George Gould, the president of the Manhattan Railway company, has written a long letter to the Board of Rapid Transit Commissioners taking vigorous exception to the franchises prepared for the proposed Manhattan extensions. Mr. Gould undertakes to show the benefits elevated roads have conferred on the city, how heavily they have been taxed and how foolish and perverse the commissioners are. The tenor of his complaint is shown by the following quotation from his letter: "The trouble with your board is, I fear, deep seated. Your mission, as you conceive it, is to furnish rapid transit, by underground railways, at the city's expense. You are wedded to that scheme. Municipal construction of tunnels in New York city is the ambition of your official existence. The constitutional debt limit of the city having been reached, your scheme becomes Utopian and impossible. Why should it longer stand in the way of grants which, were it not for your favored project, you would gladly make to this company?" Mr. Gould does not, in set terms, refuse the commissioners' franchises, but again offers to build the lines on the terms his company wishes for itself. M. S.

Canadian Intelligence.

Ottawa, April 16.—The Montreal Street Railway company is building 20 motor cars for the Kingston, Jamaica, street railway.

The Halifax, Nova Scotia, Electric Street Tramway company will spend about $50,000 in improving its plant. It has just installed two large generators.

E. F. Hutchings and others of Winnipeg, Man., ask power from the provincial legislature to construct an electric or steam railway from Winnipeg along the east side of Red River to St. Andrews Rapids.

The Ottawa Electric Light company has been given the exclusive privilege of supplying light and power in the city of Ottawa, on the condition that the price of light be reduced to 40 per cent. This is the result of an application made by the Deschenes Electric Light company to be allowed to supply light and power to the people.

In respect to the proposed motocycle service to be established between Toronto and Richmond Hill this summer, it is said the initial car will be fitted with electric lights and buttons for the use of conductors and passengers, by which a warning may be given to the motorman to turn to the right or left. It is claimed that this car will develop sufficient power to ascend heavy grades between Toronto and Richmond Hill at a speed varying from six to 12 miles per hour, carrying a full complement of passengers.

The Ingersoll Packing company has contracted with the Canada General Electric company for a complete installation of incandescent lamps, arc lamps, motors and generators for its factories at Ingersoll, Ont.

By an agreement entered into upon the commencement of the road, J. H. Beemer had a two-years' option for the purchase of the Quebec street railway. It is now said to be his intention to purchase the road and to consolidate it with the Quebec, Montmorency and Charlevoix railway. The motive power of the latter road will at once be converted from steam to electricity. Later on an extension of the line will be made to Murray Bay.

The finance committee of the council of the city of Hamilton, Ont., recently considered the application of the street-railway company for concessions. The committee decided to ask the railway company what was the value of the property, and if it was prepared to sell and on what terms. If the railway company decides that it will not sell, it is unlikely the aldermen will grant any concessions, and if the company is willing to dispose of the plant at a reasonable figure the city will purchase the road and own and run it. A. V. W.

Northwestern Notations.

Minneapolis, April 25.—It is understood that the different street-railway companies of Seattle, Wash., will be consolidated under one management this year. They have hardly paid expenses, but it is believed that with the saving that would come from a central power house and reduced forces in offices a paying investment would result.

The street-railway company has begun setting trolley posts for changing its Selby avenue cable road in St. Paul into an electric line. The device to overcome the hill will be put in June 1, and it is expected to have the line running by electricity on July 1st.

The Parkersburg Electric light company has been incorporated at Parkersburg, Ia., with $10,000 capital stock, and has just been granted a franchise by vote of the people.

One of the engines in the power house of the electric-light plant at Decorah, Ia., blew up recently. It tore away the rear part of the engine and damaged the brick wall considerably. The engineer was in another room and escaped injury.

The street-railway company at Madison, Wis., has made a number of minor changes and improvements and has added some new rolling stock.

The National Electric company of Eau Claire, Wis., shipped a car of electric-light machinery to Yokohama, Japan, recently.

The city of Rochester, Minn., is taking bids for furnishing equipment and installing it for an enlargement to the city electric plant. The plant has been overloaded for some time and has been reported to be absolutely dangerous. The boilers are worn out, and there has been a possibility of their

exploding at any time. The estimated cost of the addition is $20,000.

J. K. Tillotson of Oshkosh, Wis., has issued a prospectus of the proposed Oshkosh-Neenah line, showing that it expects gross earnings of $64,928; expenses, including a six per cent. dividend on preferred stock, $6,000, leaving a net profit on common stock of $25,594. He will apply for a franchise at Neenah at once.

The Roller Mill company of Sheldon, N. D., will put in an electric-light plant if sufficient patronage is guaranteed.

The council is considering an application for an electric-light franchise for Elkhart Lake, Wis.

The Rapid Transit company is preparing to extend its city loops in Waterloo, Ia.

L. D. Lane, proprietor of the electric-light plant at Hampton, Ia., has reduced the price on lights for business houses and dwellings.

A company is proposed at Ashland, Wis., to utilize the water power of White River and transmit it by electricity to Ashland. There is enough fall in the river to develop 1,500 horse power. Guy Cole of Beloit, Wis., is forming the company.

An electric railway line is projected between Logan and Magnolia, Ia.

The Electric Light and Power company of Oconto, Wis., was sold under a lien to Eller Pemperin.

The Winona Railway and Light company of Winona, Minn., wants permission from the council to take up the tracks to the East End and discontinue that line. The company says that unless this permission is granted it will be necessary to stop running all cars, as that line is a dead loss and under the present arrangement the whole system fails to pay expenses.

The electric-light plant of Bedford, Ia., has been completed and put in operation.

The council of Henderson, Minn., has reduced the meter rate from 12 to 8 cents per kilowatt-hour.

The Fox River Valley Electric Railway company expects to have cars running between Appleton and Menasha, Wis., soon. It will lay tracks in Neenah, as the council will grant a franchise. C.

PERSONAL

Mr. C. M. Baker has been appointed general superintendent of construction of the western division of the Postal Telegraph-cable company, with headquarters at Chicago.

ELECTRIC LIGHTING.

Bids will be received by the West Chicago park commissioners until May 24th for 218 arc lamps and 164 cut-outs and insulators. The specifications are on file in the engineer's office in Union Park, Chicago.

Mayor Harrison and City Electrician Ellicott have completed the location of the 2,000 arc lights which are to be added to the municipal street-lighting system of Chicago this year, and within 90 days 600 of them will be in service. Inside of six months all will be in use. New lights are placed in the Third to Tenth wards, Twelfth to Sixteenth, Nineteenth to Twenty-second and Twenty-ninth to Thirty-first wards, inclusive.

On the forenoon of Saturday last the plant of the Cicero Light, Heat and Power company was totally destroyed by fire, entailing a loss of $15,000. The fire was caused by sparks from a passing Chicago and Great Western engine, which lit on the roof. The building burned rapidly, and but little was saved. The company furnished light for Austin, a suburb of Chicago, and divided the western territory with the Cicero Water, Gas and Electric Light company. In the afternoon the Cicero town board made arrangements with the Oak Park Electric Light company to furnish Austin with light until the Cicero plant could be rebuilt. The necessary connections were quickly made, and Austin was lighted that night as though nothing had happened.

ELECTRIC RAILWAYS.

The committee on the District of Columbia has reported back to the House the bill for the extension of the underground system on the Metropolitan railroad in Washington, and its passage is urged by the residents along the proposed route, and is recommended by the committee.

The Marion City, Ind., Railway company, which has an electric line running from Marion to Jonesboro, and the Union Traction company of Anderson have combined to build a connection between Alexandria and Jonesboro, giving an electric line from Marion to Anderson and from Alexander to Elwood.

The Chicago City Railway company has made a formal application for permission to extend its temporary trolley line on State street north of Van Buren street and around the loop. This request is supported by petitions of business men in that part of the city. The council, it is expected, will pass an ordinance, but as Mayor Harrison refused permission under the "track elevation ordinance," it is not considered probable that he will approve the ordinance.

With a capital of $1,000,000, the Syracuse, Skaneateles and Moravia Railroad company has been incorporated to construct an electric road 40 miles long in New York through the counties of Cayuga and Onondaga, with the village of Moravia, Cayuga county, as its southern terminus, and the city of Syracuse as the northern. The directors are Wing T. Parker, Thomas W. Downing, John Andrews and Joseph Parker of Moravia and Henry J. Hibbard of Skaneateles.

Gen. John McNulta, receiver of the Calumet Electric Street Railway company of Chicago, has filed a petition asking permission to expend $60,000 in the improvement of the plant and the purchase of property for a terminal loop and transfer station at Sixty-third street and Stony Island avenue. The petition was granted. Competition between the Calumet railway and the South Chicago City railway is great, and it is necessary to extend the tracks from Sixty-fourth to Sixty-third street. It is intended to purchase the building at the southwest corner of Stony Island avenue and Sixty-third street, which will be used for a terminal loop and transfer station to the Alley "L" road. Two elevators will be put in to carry passengers to and from the Alley "L" platform.

TELEPHONE.

The Galena, Kan., Telephone company is commencing work on a telephone exchange in Weir City, Kan., which it expects to have in operation in a month or six weeks. When this plant is completed it will be connected with Galena and intermediate towns by a toll line. In Galena this company will soon replace its old 200-number switchboard with a 300-number metallic circuit board to accommodate the rapidly increasing business.

TELEGRAPH.

The Rocky Mountain Telegraph company, which has now in operation about 300 miles of line in Montana and the Northwest Territory, has been sold to the Postal Telegraph company, and on May 1st the new owner took possession.

The Canadian Pacific company has now begun to put up a new telegraph line entirely of copper along its road from Montreal to Vancouver, 2,910 miles. As the wire used weighs about 300 pounds to the mile, this will require about 390 long tons of copper.

TECHNICAL SCHOOLS.

The summer school of Cornell University, Ithaca, N. Y., will be opened on July 5th and continued until August 13th. Among other studies courses will be provided in mechanical drawing, electricity and magnetism (laboratory work) and experimental engineering. No educational requirements are stipulated for admission to this school. G. B. Preston is instructor in experimental engineering, and he can give further information as to fees and registration.

The register of the Lehigh University of South Bethlehem, Pa., for 1897-98 has been published and may be had on application to the secretary of the university. This institution has courses in civil, mechanical, mining and electrical engineering. The last-named leads to the degree of E. E. Advanced instruction is also given to graduate students. The faculty includes H. Wilson Harding, emeritus professor of physics; Joseph F. Klein, professor of mechanical engineering; William S. Franklin, professor of physics and electrical engineering, and Dr. Alexander Macfarlane, lecturer on mathematical physics.

Entrance examinations for admission to the Massachusetts Institute of Technology of Boston will be held at the institution and in a number of other places on June 30th and July 1st. In the West examinations will be held in Belmont, Cal., Chicago (in charge of Dr. H. H. Belfield at the Chicago Manual Training School, Michigan avenue and Twelfth street), Cincinnati, Cleveland, Denver, Detroit, Louisville, St. Louis and St. Paul. A second series of examinations will be held at the Institute in Boston for those unable to be present at the first. Detailed information is sent on request by the secretary of the school, H. W. Tyler.

ELECTRICAL SECURITIES.

The gross receipts of the Chicago Edison company for April were 20 per cent. greater than for the corresponding month for last year.

The passenger earnings on the Brooklyn Heights railroad system for April were $470,780, an increase of $48,485 over the corresponding month last year. The earnings on the Nassau system for the same period were $166,796, an increase of $25,356 over the same period of last year.

The first quarterly report of the Metropolitan Street Railway company of New York shows a remarkable increase in the gross receipts, the figures for 1898 being $2,423,255, against $2,002,462 for the first three months of last year. After paying all expenses of operation and fixed charges, the company shows a net surplus of $423,960 on the quarter's business.

The New Orleans Traction company reports gross earnings for March of $112,807, a decrease of $5,530 as compared with the same month of last year, and net $47,759, an increase of $1,489. For the three months ended March 31st the gross earnings were $332,374, an increase of $14,688 as compared with the corresponding period of last year, and net $141,705, an increase of $30,339.

The North Shore Traction company of Boston reports gross earnings for March of $105,960, an increase of $6,915 as compared with the same month of last year, and net $42,846, an increase of $6,606. For the first three months of the year the gross earnings were $288,681, an increase of $9,186 as compared with the corresponding period of last year, and net $85,699, a decrease of $6,458.

The Bridgeport, Conn., Traction company reports gross earnings for April of $25,900, an increase of $1,471 as compared with the same month of last year, and net $10,411, an increase of $2,439. For the 10 months ended April 30th the gross earnings were $273,817, an increase of $11,221 as compared with the corresponding period of last year, and net $124,197, an increase of $21,984.

The Columbus, Ohio, Street Railroad company reports gross earnings for April of $51,422, an increase of $5,962 as compared with the same month of last year, and net $24,602, an increase of $1,227. For the four months ended April 30th the gross earnings were $204,540, an increase of $21,749 as compared with the corresponding period of last year, and net $104,773, an increase $10,572.

TRADE NEWS.

The Link-belt Machinery company, Chicago, has recently established a branch office at 521 Seventeenth street, Denver, Colo. Mr. A. E. Lindrooth, the engineer in charge, will look after the company's interests in Colorado and adjacent states and territories.

Mr. Charles Blizard of New York, manager of the Electric Storage Battery company, has been remembering his many friends in the trade by presenting to each a box of thumb pins, to be used upon drawing tables, for securing blotters to desks and the like.

Stone & Webster, the electrical experts and engineers of Boston, announce that they have recently made arrangements with Prof. S. Homer Woodbridge by which his business of heating, ventilating and sanitary engineering will hereafter be intimately associated with their own electrical engineering work.

The city of Union Springs, Ala., is about to install an electric-light plant. The engine is to be a Ball engine, built by the Ball Engine company, Erie, Pa. Mr. Charles Doughty, Randolph, Mass., has recently ordered for his electric-light plant at Randolph, Mass., a 200 horse power vertical cross-compound Ball engine direct-connected to a 120-kilowatt generator.

The Buckeye special coiled-filament lamp has lately been given thorough and scientific test for watt consumption, candle power maintenance, etc., at periods of 200, 400 and 600 hours, on the lines of a number of central stations and isolated plants. The results were very satisfactory. The Buckeye Electric company contends that it "pays to deliver what you sell." Catalogue and prices are sent on application to the Chicago office, 753 Monadnock building.

The Sprague Electric company "points with pride" to its Alley "L" railway equipment in Chicago, now partially in operation. It is claimed that the old service will be given with 15 per cent. less cars by reducing the time schedule, as can be done by the perfectly controlled electric cars. The Sprague company also announces the equipment with Lundell driving motors of the plant of "The Galvanoplastic" in Berlin, and states that motors have also been shipped in considerable numbers to India and Japan.

Geo. W. Patterson reports that the two companies he represents—the American Circular Loom company and the Gordon-Burnham Battery company—have removed their Chicago offices from 1114 to 1539 Marquette building, and invites all old friends and customers to come up and have a birdseye view of the city. The conduit business, Mr. Patterson says, was never so good before, and is increasing, while the merits and low prices of the Phenix batteries are beginning to be recognized in a flattering manner.

The Westinghouse Electric and Manufacturing company is building two three phase belt driven generators, each of 500 horse power, 3,000 alternations and 2,400 volts, for the Canadian Niagara Power company at Niagara Falls. The success of the 5,000 horse power machines built for the Cataract Construction company has encouraged others to enter the field for harnessing Niagara, but, like the pioneers, the new comers seem to go to the

Westinghouse company for the apparatus which makes these operations possible.

The Western Electric company has issued a 24-page pamphlet on tools which contains a complete list of lineman's and construction tools, all of which can be furnished from stock. Everyone interested in the construction of electric lines should have a copy, and the Western Electric company will mail one upon request to anyone desiring it. This pamphlet is known as Tool Catalogue No. 3.

Always alert and energetic, the Warren Electric and Specialty company of Warren, O., the "anti-trust" incandescent lamp maker, is now rallying its friends to aid it in selecting a name for its lamp. It explains that the name "Warren" has led to some confusion in the electrical business, and so it wants a new name. "It has seemed fitting to us that our patrons should decide this matter for us," says the company, "and in order to make the matter of sufficient interest to them to induce them to do so, we offer prizes for the best and most appropriate name as follows: First prize for the name which the judges decide is the best and most appropriate, $50 cash; second best, $30; third best, $20; fourth best, $10. Blanks will be furnished to be filled out and sent to us. The contest will be open from May 1st to November 1st, next, at which time a decision will be rendered and each contestant will be notified of the result, and checks sent to the successful ones."

BUSINESS.

Recent circulars of the Walker company relate to switchboards for isolated plants, the Walker underground electric railway conduit, Walker pivotal trolley and railway switchboards.

The Illinois Electric company, Chicago, desires to inform the trade that it has a complete line of Crefeld weatherproof, annunciator, office and magnet wires and is in position to fill orders promptly.

The Whitin Machine company of Whitinsville, Mass., has just completed a new casting shop which will be entirely fireproof. It is furnished by the Berlin Iron Bridge company of East Berlin, Conn.

Huebel & Manger of Brooklyn are kept busy getting out rush orders from all parts of the country. The outlook is very promising, and they expect to sell more bells and push buttons this year than ever before.

The Westinghouse company calls attention to its alternating-current fan motors for the season of 1898. These are induction motors, well finished, and made for 50 or 100-volt circuits and 7,200 or 16,000 alternations per minute.

The La Porte Telephone company of La Porte, Ind., has just installed a 300-line Stromberg-Carlson rapid-operating switchboard and completely changed from automatic to a manual system. It is said that greatly improved service has resulted from the change and that it is giving the company many new subscribers.

"A magnificent new train, and one that is ahead of any ever built." Such is the comment of people who have seen the New Pennsylvania Limited which leaves Chicago Union Station daily, at 5:30 p. m., over Pennsylvania Short Lines. H. R. Dering, assistant general passenger agent, 248 South Clark street, Chicago, gives details.

J. H. Cooke, 753 Monadnock building, Chicago, reports a lively inquiry for and many sales of the Jandus enclosed alternating arc lamp. Steady burning, high efficiency and absolutely noiseless operation are qualities that attract the central-station managers. Special information, prices and catalogues are sent on application.

The Westinghouse Electric and Manufacturing company has sold to the Citizen' Street Railway company of Indianapolis a 500-kilowatt machine of the Westinghouse standard type. The machine is direct-connected to an Allis Corliss engine and makes 90 revolutions per minute. It is over compounded 10 per cent., the normal potential being 550 volts.

The Empire Lamp Works, manufacturers of miniature electric lamps, announce the removal of their factory and office from 154 West Twenty-seventh street, New York city, to 124 Monticello avenue, Jersey City. The new quarters can be easily reached by way of the Pennsylvania ferries from Cortlandt, Desbrosses and Twenty-fourth street ferries to Jersey City, and thence by the Monticello avenue trolley cars, right to the door, a ride of 15 minutes from the ferry.

The American Tool Works company of Cincinnati, O., reports that the demand for machinery in foreign countries is still steady, notwithstanding the fact that hostilities between this country and Spain have begun. The company has received a number of orders through its London office, among them being one from J. Stone & Co. of Deptford, England, for a line of brass-working machinery, including valve milling machines, monitor lathes and cock grinders; also an order from Furnival & Co. of Raddish, England, for a number of standard engine lathes, drill presses and shapers.

The new air-tight open-circuit battery called the Badt hermetic cell is receiving the approbation of all engineers and electricians who have been obliged to deal with the troublesome question of primary batteries. The oil seal, which so positively prevents the evaporation of the liquid, the creeping of salts and the constant premature disintegration of zincs, is the latest novelty in batteries and is a feature which strongly recommends this cell for use. The Western Electric company of Chicago, which recently announced that it was headquarters for batteries of various kinds, desires to state that the Badt hermetic cell is also added to its list of batteries.

K. McLennan & Co., Chicago, sole manufacturers of the well-known Gale commutator compound, have found it necessary to remove to larger and more commodious quarters, owing to the increased demand for their product. This compound, it is said, is now in use not only all over the United States, but in every foreign civilized country as well. The compound is said to give entire satisfaction, and this accounts for its great demand. The success of the company is due in no small measure to the able management of Martin J. Isaacs, whose aim it has been to make Gale's commutator compound known all over the world. That he has succeeded is evident from the fact that orders are received daily from all over the world. The McLennan company is now located in a fine suite of rooms in the Title and Trust building, 100 Washington street. The company has heretofore been located at 1128 Marquette building.

Seventy-six double equipments of type 49 35 horse power motors have been ordered from the Westinghouse Electric and Manufacturing company by the Cleveland Electric Street Railway company. Westinghouse street-railway motors have achieved a degree of success that has made them standard. Charles H. Smith, superintendent of the Lebanon and Annville (Pa.) Street Railway company, writes: "On June 20, 1895, one of the Westinghouse 12-A 30 horse power equipments was put into service on this road. Since that time it has made 592 days, 200 miles a day, a total mileage of 118,400, without a single repair to any part of the machine, save renewal of brushes and bearings. The motors were put under a Jackson & Sharp 30-foot closed body car, running over the hardest part of our road, with less than five minutes' lay-over at either terminal from six a. m. to 12 midnight. We wish all our equipments were Westinghouse 12-A."

ILLUSTRATED ELECTRICAL PATENT RECORD.

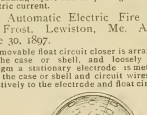
Issued May 3, 1898

603,263. Process of and Apparatus for Electrolytic Tanning. Edward Davis, Philadelphia, Pa., and Horace R. Mustard, Smyrna, Del. Application filed July 27, 1896.

In the art of electrolytic tanning the process consists in, first, purifying water by electrolysis, then bleaching with the water, then electrolyzing the tanning liquor obtained from leaching, then suspending the skins to be tanned in the tanning liquor and subjecting them to the action of an electric current.

603,270. Automatic Electric Fire Alarm. Walter E. Frost, Lewiston, Me. Application filed June 30, 1897.

A movable float circuit closer is arranged centrally within the case or shell, and loosely supported on diaphragm a stationary electrode is metallically connected with the case or shell and circuit wires are connected respectively to the electrode and float circuit closer.



No. 603,270.

603,283. Electric Arc Lamp. Timothy H. Pettengill, Amsterdam, N. Y. Application filed September 7, 1897.

Included in this combination with the coarse and fine wire coils, the starting coil, bridge contacts and circuit connections, are the armature lever, an insulated cut-out contact carried thereby, a circuit connection from the contact to the terminal of the coarse coil adjacent to the bridge contacts, and a short-circuiting contact against which the first-named contact is drawn when the armature lever is brought to its lowest position.

603,286. Electroplating Apparatus. Louis Potthoff, Flushing, N. Y. Application filed April 22, 1897.

This apparatus is intended for electroplating wire, and comprises a framework carrying rollers, a conducting comb carried by the framework for conducting current from the wire-can I for maintaining separate terms of the wire apart, a vat containing the frame-work, comb and rollers, one or more anodes contained in the vat, and circuit connections to the anode or anodes and comb.

603,334. Electrical Attachment for Gas Lights. Franklin L. Kellner and George S. Barrows, Philadelphia, Pa. Application filed November 22, 1897.

This attachment is particularly adapted for Welsbach lights. A valve is provided with a gaway and adapted to be lifted and turned to position by a plate like armature is connected with the valve and electromagnets, and means for lifting, rotating and quickly dropping the valve are provided.

603,369. Electric Signal System. Louis C. Werner, Broad Brook, Conn. Application filed June 12, 1897.

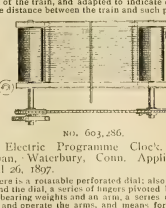
The conductor extending along the line of way is insulated from the track, and a current collector is provided which is automatically reversible, while in contact with the conductor, by the reverse movement of the vehicle, and comprises a carrier arm pivotally connected with the vehicle and a triangular sliding contact shoe pivoted to the carrier arm and reversible, on the reversal of the movements of the vehicle, to bring its different sides into engagement with the conductor

603,383. Electric Arc Lamp. Alfred W. Knutson, Galesburg, Ill. Application filed April 30, 1897.

A clutch for electric arc lamps having a clutch arm provided with a rod opening, and a movable auxiliary grip-jaw supported on the arm and normally moved in an inward direction, is one of the features described.

603,390. Electric Signal System. Louis C. Werner, Broad Brook, Conn. Application filed June 17, 1897.

A visual electrical indicator is carried by the train and in circuit with the current collector and responsive to every variation in the length, and hence in the resistance, of the conductor between the vehicle and the distant points within the range of the indicator, and having an indicator hand movable at either side of a normal, idle, central position in accordance with the direction of movement of the train, and adapted to indicate every variation in the distance between the train and such point.



No. 603,286.

603,450. Electric Programme Clock. James O. Lyman, Waterbury, Conn. Application filed April 26, 1897.

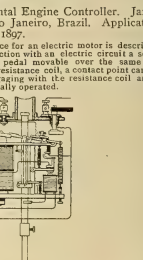
There is a rotatable perforated dial; also a contact plate behind the dial, a series of fingers pivoted below the dial, and bearing weights and an arm, a series of cams to engage and operate the arms, and means for intermittently rotating the cams to successively lower and raise the fingers.

603,515. Electrical Apparatus. William Stanley, Pittsfield, Mass., assignor to the Stanley Instrument company of Massachusetts. Application filed January 28, 1897.

Two coils are in series with each other and with a source of alternating current, in combination with two shunts, one of less, the other of greater time constant than the coils which they respectively shunt, and a closed-circuited armature is in direct inductive relation to the fluxes produced by both coils.

603,524. Electric Dental Engine Controller. James J. Coachman, Rio Janeiro, Brazil. Application filed August 21, 1897.

A controlling device for an electric motor is described, comprising in connection with an electric circuit a series of contact strips, a pedal movable over the same and carrying contacts, a resistance coil, a contact point carried by the pedal for engaging with the resistance coil and a pole changer electrically operated.



No. 603,284.

603,534. Time Limit Cut-out. Henry H. Cutler, Chicago, Ill. Application filed July 26, 1897.

One claim is given in combination with a motive coil of a cut-out and a time limit controlling the same and comprising a section of an electric circuit the resistance of which varies with rise of temperature due to the current.

603,606. Electric Conveying System. Alvaro S. Krotz, Springfield, Ohio. Application filed December 2, 1897.

The combination is claimed of a battery or other source of electrical supply, track conductors, one connected with one pole of the latter, a plurality of terminals stationed along a continuous stretch of the other track conductor and all connected with the other pole of the battery, and automatically opening circuit closers to connect the terminals respectively with the latter track conductor.

Western Electrician.
EVERY SATURDAY.
Vol. XXII. CHICAGO, MAY 21, 1898. No. 21

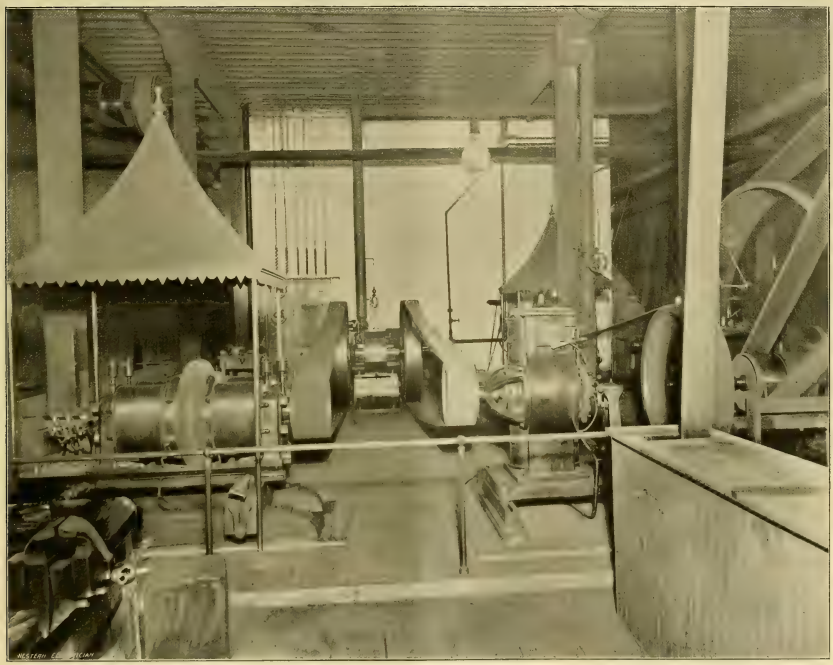
Lighting Plant in Railway Shop.

An interesting feature of the equipment of the mechanical department of the Chicago City Railway company is the electric plant which furnishes current temporarily for lighting the building on Dearborn street, between Twentieth and Twenty-first streets. The plant is of the conventional type, and, so far as the generators are concerned, presents no novel features. They are old-style machines, which were pressed into service, pending the extension of the mains from the big power houses to the downtown district. But they disprove many of the statements that have been made by makers of later machines, who contend that old types of apparatus are necessarily inefficient and unreliable. For the service required the plant at the City railway shops is admirably adapted and is certainly satisfactory to the company.

The picture on this page gives an excellent view of the machines. Two are dynamos are belted directly to a 75 horse power Ideal engine, made by A. L. Ide & Son of Springfield. One of these machines is an old Brush dynamo, shown at the left in the foreground of the picture. It carries 35 arc lamps and furnishes current at 2,500 volts. The Excelsior dynamo at the right, which is belted to the same engine, carries 40 lamps. The incandescent system is supplied from a Thomson-Houston dynamo, driven at 1,250 revolutions per minute, and furnishing current at 110 volts. This machine is in the background to the right and is partially hidden from view by the Excelsior dynamo. It is belted to a counter-shaft driven by a Jerome Wheelock engine which has a capacity of 125 horse power. The rest of the power produced by this engine is utilized in the shops.

The marble switchboard in the background contains the usual equipment of instruments. They are of the Standard Electric and Weston Instrument companies' make. A Brush current governor completes the equipment.

The lamps which are supplied with current from this plant are distributed throughout the shops. The incandescent lamps are mainly used in the pits and in the upholstering department, the arc lamps supplying the machine rooms. The plant was installed by the mechanical and electrical departments of the Chicago City Railway company last fall and has worked satisfactorily throughout the winter months.



LIGHTING PLANT IN RAILWAY SHOP.

New Electrically Lighted Trains on the St. Paul Road.

Two fine new limited trains have been built for the Chicago, Milwaukee and St. Paul Railway company and are about to be put into service between Chicago and St. Paul. The cars are electrically lighted, as might be expected from the pioneer railroad company in the West in the matter of electric train-lighting. A Westinghouse engine-dynamo is carried in the forward end of each baggage car, the steam being secured through a flexible coupling with the locomotive boiler. In addition an auxiliary storage battery is placed under each car, sufficient to supply a portion of the lamps for several hours in case of an emergency. The usual berth lights and ceiling clusters are provided, and in addition there are overhead lamps in the car vestibules. The ladies' toilet rooms are provided with electric curling-iron heaters.

Electrical Work in the Navy.

In the naval appropriation bill as passed by Congress and approved by the president are included the following items of electrical construction:

For repairing and improving the telephone line connecting the Navy Department and the Washington navy yard with the naval proving ground at Indian Head, to be immediately available, $10,000.

Addition to electric-light system at the Brooklyn navy yard, $15,000.

Steam generator for heating purposes and electric plant at the League Island navy yard, $5,500.

Improvement to the Washington navy yard electric plant, $16,000.

Toward the enlargement of the electric plant and concentration of steam at the Norfolk navy yard, $10,000.

Electric light and power plant at the naval station at Port Royal, South Carolina, $20,000.

Extension of the electric system at the Mare Island navy yard, $15,000.

Electric-light plant, Puget Sound naval station, $9,800. Establishing telegraphic communication at the same place, $4,000.

For the installation of electric-light plants in gunboats numbered 10, 11, 12 and 13, $40,000.

Wood Lake, Minn., is considering electric lighting.

National Electric Light Association.

A meeting of representatives of the electrical interests of Chicago was held at the Edison building, 139 Adams street, on Monday, May 18th, in response to an invitation from President Insull of the National Electric Light association. The following-named gentlemen were present: Messrs. S. Insull, O'Hara, Ferguson, Wallace, Donohoe, Wiley, Coster, Badt, Comstock, Munson, M. J. Insull, Wilmerding, Sunny, Low, Clark, Kittle, Gorton and Kammyer.

President Insull explained that the meeting had been called for the purpose of providing for the reception and entertainment of the visiting members of the National Electric Light association at the convention to be held in Chicago on June 7th, 8th and 9th. It had been decided, he said, to make the convention as much of a business meeting as possible, and for this purpose an excellent programme had been prepared. Among the special features for which arrangements had been made were the following:

PAPERS.

"Cost of Generation and Distribution of a Unit of Electricity." By Calvin W. Rice.

"General Distribution from Central Stations by Alternating Currents." By Herbert A. Wagner.

"General Distribution from Central Stations by Direct Currents." By Louis A. Ferguson.

"Public Lighting with Relation to Public Ownership or Control." By Alex Dow.

"Transformer Economy." By Winder Elwell Goldsborough.

"Cost of Producing Electric Power by Water Power from Lachine Rapids, Canada." By W. McLea Walbank.

TOPICS FOR DISCUSSION.

"Legislative Policy as to Public Service Corporations."

"Prices and Discounts for Electric Current, and Methods of Charging Customers."

"Standardizing Apparatus for Central Station Use."

"Standardizing Specifications for Incandescent Lamps."

"Freight Rates on Electrical Apparatus."

LECTURE.

"Electricity Direct from Coal." By Joseph Wetzler.

It was announced that the eastern delegation would reach Chicago on Monday, June 6th, and it was accordingly decided to hold an informal reception at the headquarters of the association in the Auditorium on Monday evening. It was thought that this would be an excellent way to have the visiting members meet the local central-station men and representatives of the allied interests.

Mr. Sunny suggested that a committee of 25 to be known as the reception committee, and to be composed of representatives of electrical interests in Chicago, be appointed for the purposes of receiving and entertaining the visiting members, and for the purpose of providing necessary funds for this purpose. This proposition met with general approval, and the following-named gentlemen were appointed for that purpose:

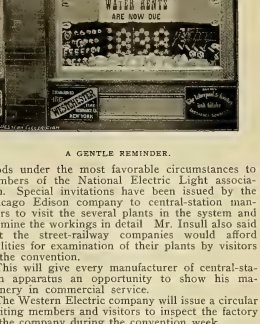
J. Holt Gates of the Walker company.
J. B. O'Hara of the Western Electrician.
L. A. Ferguson of the Chicago Edison company.
N. R. McLeod of Washburn & Moen Manufacturing company.
J. B. Wallace of the Wallace Electric company.
F. E. Donohoe of the American Electrical works.
J. R. Wiley of the Standard Underground Cable company.
M. Coster of the Westinghouse Electric and Manufacturing company.
F. B. Badt of Meysenburg & Badt.
L. K. Comstock of the Western Electric company.
Charles Munson of the Fort Wayne Electrical corporation.
M. J. Insull of the C. & C. Electric company.
F. W. Kohler of the Northern Electric company.
C. H. Wilmerding of the Crocker-Wheeler Electric company.
W. A. Kreidler of the Western Electrician.
W. H. McKinlock of the Metropolitan Electric company.
G. A. McKinlock of the Central Electric company.
B. E. Sunny of the General Electric company.
W. W. Low of the Electric Appliance company.
F. H. Clark of the Electric Storage Battery company.
Samuel Insull of the Chicago Edison company.
F. S. Gorton of the Chicago Edison company.
E. B. Kittle of the Sprague Electric company.
George C. Bailey of the J. A. Roebling's Sons company.
A. S. Hibbard of the Chicago Telephone company.
Mr. Wilmerding was elected chairman of this committee.

The chairman was authorized to appoint a committee of four to act with him as a finance and entertainment committee. This committee will report at a later meeting of the whole committee on a programme for entertainment and on ways and means. The chairman of the general committee, Mr. Wilmerding, appointed, as this committee, B. E. Sunny, M. Coster, J. B. Wallace and L. A. Ferguson.

John Jay Abbott of the Chicago Edison company was appointed secretary of the committee.

It was decided to meet again at the office of the Chicago Edison company, 139 Adams street, on Monday, May 23d, at 3 p. m.

Mr. Insull, on behalf of the Chicago Edison company, has extended a general invitation to manufacturers and agents having apparatus and supplies of any kind in use in the Edison system to invite friends and customers to inspect these products in actual operation. He said the company would gladly furnish facilities to others, and supply current for operation, in order that every manufacturer would have an opportunity of showing his goods under the most favorable circumstances to members of the National Electric Light association. Special invitations have been issued by the Chicago Edison company to central-station managers to visit the several plants in the system and examine the workings in detail. Mr. Insull also said that the street-railway companies would afford facilities for examination of their plants by visitors to the convention.



A GENTLE REMINDER.

This will give every manufacturer of central-station apparatus an opportunity to show his machinery in commercial service.

The Western Electric company will issue a circular inviting members and visitors to inspect the factory of the company during the convention week.

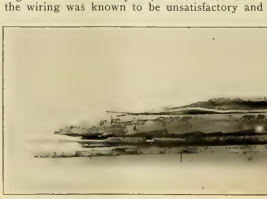
It is expected that there will be a large number of ladies in attendance at the convention, and for their special benefit there will be several trips in tally-ho coaches about the parks and boulevards of Chicago while the convention is in session. It is believed that this will prove an attraction to the ladies visiting the city at that time.

A. S. Hibbard of the Chicago Telephone company has placed the company's service at the disposal of the members of the association during the convention.

Electrical Fire at the Union League Club.

Electricity is made the scapegoat for many fires with which it has no connection, but there still remain too many cases of damage by fire due to some wiring defect. A case in point, where the condition of the wiring was known to be unsatisfactory and origin of electrical fires are usually destroyed. No trace of the annunciator wires was found near the place where the fire was started. It is believed that the fire smouldered for 24 hours before it was discovered. A toilet-room is near the location of the fire, and it is possible that a slight leakage of water was the ultimate cause of the short-circuit.

The building of the Union League Club contains an isolated electric-lighting plant that was installed about 10 years ago, when the art of interior wiring was comparatively crude. The plant is now being remodeled and rewired, but it was the irony of fate that the wireman had not quite reached the bad spot between the fourth and fifth floors at the time of the fire.



ELECTRICAL FIRE AT THE UNION LEAGUE CLUB.—BURNED-OUT MOULDING.

where a fire of clearly electrical origin ensued, was the fire at the Union League club-house in Chicago on May 13th. This fire was discovered at 11:30 a. m., and was extinguished by the firemen without great difficulty, not, however, until damage to the extent of about $2,000 had been done to woodwork, furniture and carpets. Investigation clearly revealed the fact that the trouble was caused by a cross between a 110-volt house-lighting circuit and annunciator wires in the space between the fourth and fifth stories of the building. The lighting circuit was of No. 14 wires, rubber-insulated and placed in a wooden moulding. The accompanying illustration shows the charred moulding and burned-out wires of the offending circuit as they appeared after the fire, showing where the arc occurred. It is interesting, because all traces of the

A Gentle Reminder.

In Chillicothe, Ill., the electric-light and water works are operated by one company, and like many other similar concerns it takes considerable pride in its establishment. It is customary to make a display in the company's window, and the brilliant illumination seldom fails to attract a crowd. During the month of April there was a particularly attractive display of electrical fixtures arranged artistically and a design with the figures 1898 picked out in incandescent lamps. The window itself was made to represent a frame and was studded with incandescent lamps. The manager of the company took advantage of the opportunity afforded to remind his fellow townsmen that a certain formality should be complied with in order to continue the service, so a sign was placed in a most conspicuous position (as shown in the picture) announcing that "Water Rents are Now Due."

The Inventor of the Telectroscope.

The Polish schoolmaster who is said to have invented an instrument by which one is enabled to see an object at a great distance by the electrical transmission of light-wave impulses has been interviewed. This instrument is said to do for light what the telephone does for sound. It has been considered a possibility by several inventors, and a number of experiments have been made to secure the desired result, but if the newspaper reports are true Szczepanik is the first to reach the goal. His instrument is known in English as the telectroscope. The Germans, with their patriotic preference for the home product in word building, call it the fernseher, or "far-seer." The interview referred to is printed in Black and White, an English weekly journal, and is interesting if not important:

My first impression of Szczepanik, as I met him at the house of his financier, Herr Ludwig Kleinberg, at Vienna, was that he could be anything but an inventor, though I don't suppose anyone has ever been able to detect an inventor by mere external appearance. He might be a struggling musician, a student or a shopman. I think my second was that there was a singular naïveté in this erstwhile village schoolmaster, who, just over the threshold of 25, had in a night sprung into fame. Szczepanik is of medium height and of sturdy build. His speech comes quickly, though his natural Polish volubility is somewhat curbed by the idiomatic difficulties which German presents to him. He gesticulated freely as he spoke, and paced up and down the room preferably to sitting. He wore an incongruous kind of dress of black—the usual continental compromise between evening dress and an English artisan's "Sunday best." His voice was soft, almost childish; his manners gentle and kind; but until one won his confidence his demeanor was reserved to the point of shyness. His modesty and bland simplicity are remarkable and irresistibly draw you to one of whom his financier remarked to me: "He is an unspoiled child of nature. He does not know his own greatness, and his modesty is charming."

Herr Kleinberg is said to have made the acquaintance of this gifted stripling casually in a Vienna cafe as he passed through that fitful "Sturm und Drang" period, destitute of everything but his wonderful ideas.

"You must be an incessant worker, Herr Szczepanik," I said to him.

"Yes, I am practically always at work, though it is only in the night that my mind can be said to be most fruitful. Do I miss my sleep? Not a bit! If an idea comes to me I must get up and clinch it, and I believe I alarm my friends by the enor-

mous number of cigarettes I consume in the nocturnal hours. My memory, however, works, as it were, on certain lines, and though I should never forget the details of a machine that I have once seen, I might easily forget an everyday incident where others could not possibly do so. I jot my ideas down in notebooks. My friends laugh at me about those books. I never know when an idea is going to strike me, and walking along the streets my companions are sometimes astonished to find that I have disappeared. What my particular sphere of inventive work is I cannot say. My mind is omnivorous. My invention which revolutionized silk-weaving was discovered, for instance, without my scarcely knowing what a weaving-loom was."

"How did you first discover yourself, so to say?"

"I don't know. I dabbled in invention as a child —made ships and whatever came to hand. My technical knowledge is almost all practical and acquired haphazard. It is true, I studied physics, but never gained any distinction, and I am afraid I made a good many enemies." He smiled reminiscently. "I used to spring problems upon the professors, even in my examination papers, and they didn't like it. Then I took up the subject of photography, and had the mortification of seeing several things patented which I had also invented. The finder in the kodak, that's one; the electrophonic piano, that's another. How did I hit upon the telectroscope? Oh, the idea is by no means a new one. My attention was first called to it by reading Professor Liesegang's 'Beiträge zum Problem des Elektrischen Fernsehens.' I hit upon the idea of employing oscillating mirrors. I do not say that my instrument is perfect. Was photography perfect, was the telephone or the telegraph perfect when first introduced to the public? Well, it must be relatively the same thing with the telectroscope. But I claim to be able to show a true picture of the object—be it a written-out telegram or a battle —with all the clearness of the cinematograph."

Szczepanik tacitly agreed with me that the effect of observation upon the mind of an inventor was to render him virtually a pessimist. He would see defects and shortcomings in everything which came within the range of his reflective powers. "I am myself a skeptic concerning physical forces," says Szczepanik. "For instance, I question sometimes whether color exists in nature. I believe the sensation of color is due to a certain condition associated with optics. Hence, I fear we shall never be able to obtain more than a limited success in color-photography, simply because, in my opinion, you can never more than relatively approach those conditions prevalent in the human eye. My aim in physics is simplicity, and to exclude the unnecessary and superfluous. Unfortunately, it takes years and years of this exclusive process before mankind has finally reached that goal which is perfection."

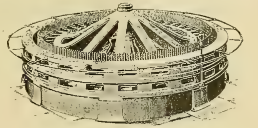
The English electrical papers insist that no material advancement has been made. The London Electrical Engineer, for instance, in its last issue, commented as follows: "Mr. Paul Schmidt gives in a Vienna paper further details of Herr Szczepanik's invention, with a diagram of connections which is unintelligible. The gist of the whole article lies in the last paragraph, which practically states that the inventor has abandoned selenium as unsatisfactory, and that he is experimenting on a more sensitive compound of his own. When this is a success more details will be given. We remember that the last time we prophesied that an inventor was stating his ideas as facts without first trying them, we were threatened with personal violence. In spite of this, we do not mind venturing the prophecy that so far Herr Szczepanik has carried out no successful experiment, but has confined his attention to romancing to untechnical reporters."

Fritz Koettiger of Fountain City, Wis., contemplates establishing an electric-light plant.

Electric Power Transmission at Bellegarde.

In 1871 an English-American syndicate obtained a franchise for exploiting the hydraulic power of the Rhone at Bellegarde, about 32 kilometers from Geneva, Switzerland, but the system of power transmitted by cables did not prove satisfactory, and electrical transmission has since been substituted to the advantage of all concerned.

The power-station is at the union of the Valserine and the Rhone. Immediately above Bellegarde the Rhone is quite narrow, being only from five to 20 meters in width, and its course for that distance is nearly straight, especially at the narrowest part. Formerly the river at this point became subterranean for a short distance, but in order to make a better and safer route for the water during freshets the overhead rocks were blasted away, and the Perte du Rhone is no longer a tourists' wonder. Here, at high water, the flow is about 1,275 cubic meters per second. The hydraulic canal commences immediately



800 Horse Power Alternator.

ELECTRIC POWER TRANSMISSION AT BELLEGARDE.

above the rapids and runs about 150 meters on the surface, having a width of 20 meters average and a depth of 2.5 meters, separated from the river by a dike of masonry. This is followed by a tunnel 550 meters long, excavated through a hard, chalky formation, having a width of nine meters at base and 6.5 meters depth, or 56 square meters of cross section.

Three gates at the entrance of the tunnel regulate the admission of water, which is afterward led to a reservoir of 1,500 cubic meters capacity, at the rear of the station, where it passes the turbines and returns to the river.

The maximum volume of water which passes through the tunnel is 100 cubic meters per second. The fall is 12 meters at the turbines at low water, and from 11 to 10 meters at mean and maximum flood. Assuming 75 per cent. efficiency for the turbines, the efficiency at the driving axles would be as follows:

	Volume.	Fall.	Power.
Low water.	60 cubic meters	12 m	7,200 H. P.
Mean water	80 " "	11 m	8,800 "
High water..............	100 " "	10 m	10,000 "

In view of the possible changes in the bed of the river, it is intended to build a wing dam to turn more water into the canal in case of necessity.

The station originally included three turbines, having a total of 2,000 horse power—two of 600 each and one of 800. One is 2.5 meters in diameter, making 90 revolutions per minute, and the others are now making 130 revolutions, being direct-connected to triphase alternators.

Of these alternators one has a capacity of 800 horse power. The field of 44 poles is mounted on a steel wheel cast in one piece, 3.85 meters in diameter. The armature is carried on a fixed crown, and has a diameter of 4.6 meters. The total weight of the machine is about 22 tons, or nearly 40 kilogrammes per kilowatt, for the output is 400 amperes at 1,050 volts. The frequency is $47\frac{1}{2}$ periods, and the efficiency 95 per cent. The exciter is a 20-kilowatt machine, actuated by a separate turbine, and absorbs about 3.5 per cent. of the power. Considering the fact that the original installation of turbines was not thoroughly the best for the present purpose, these figures are not excessive in the present adaptation.

Two new dynamos have been installed of 1,200 horse power each, direct-connected on the turbines. The station is sufficiently large to admit of further additions to raise the total to 8,000 horse power. A 15-ton traveling crane is also in contemplation as part of the station equipment. Arrangements have been made so that, with three separate superposed wheels and automatic regulation, the best advantage can be taken of the various heads of water. The diameter of these wheels is three meters, the speed 114 revolutions and the efficiency 75 per cent.

The two 1,200 horse power dynamos have each an exterior diameter of six meters and the inner moving part of five meters. The capacity is 350 amperes at 2,000 volts, and the total weight is 42 tons. The installation is completely protected by lightning arresters, a very necessary precaution in that stormy, mountainous region.

The distribution of the energy developed in the initial plant is interesting, as the table herewith shows:

	Distance of transmission	H. P. delivered	No. of motors.
Phosphate of lime mills ...	[illegible] meters	200	3
Phosphate of lime mills......	[illegible]	90	2
Cotton mill	[illegible]	[illegible]	3
"Batiste" fiber mill ...	[illegible]	250	[illegible]
Paper mill........	200 "	120	cable transm.
Calcium carbide works	[illegible]	[illegible]	1
Saw works	[illegible]	[illegible]	[illegible]
Total	[illegible] meters	[illegible]	

To deliver 2,500 horse power from the dynamos it is necessary to develop 3,200 horse power at the turbines, 2,000 of which can be furnished by the old cable transmission system. The mean loss is eight per cent. in the alternators, four per cent. in electric transmission and eight per cent. in the motors, a total of 20 per cent., as against 30 per cent. in cable transmission.

One of the most interesting of the installations in this system is that which furnishes power for operating a cotton mill. One floor contains the looms and the triphase motors, these latter being well removed from dust and housed in a separate apartment. Three motors are used, one to run the fan and the machine shop, while the others drive the shafts. One of the pair runs the preparatory machinery, carders, combers and spoolers; the other operates the looms. These two motors absorb 80 amperes at 1,000 volts, make 350 revolutions and are self-regulating between 120 and 170 horse power. The first consumes between 15 and 30 horse power.

Through the medium of a transformer current is furnished for 360 lamps of 16 candle power, 300 of which are in the spinning loft.

The price charged for current varies with consumption, from 100 to 50 francs per horse power year. The power is available 7,500 hours per annum, the continuous user paying from 0.67 to 1.33 centimes per horse power hour. If power is used at the rate of 11 hours for 300 days, the price is greater.

Vertical Section.

ELECTRIC POWER TRANSMISSION AT BELLEGARDE

Alley "L" Electrically Operated.

On Monday 52 of the cars of the South Side Elevated Railway company, Chicago, were electrically operated. These cars are supplied with current from the company's power house at Fortieth and State streets, now nearly completed, and are run in trains composed of from two to five cars. Each car has its own contact shoes, motors and controlling apparatus, but all the cars in a train are operated from the head car (although the motorman could control the train from any car) by Frank Sprague's multiple-unit system of control. The electrical trains are interspersed among trains drawn by the old steam locomotives, and the train service is consequently partly steam and partly electric and will continue to be such for a short time, with a gradually decreasing number of steam trains, until all the cars are electrically equipped and the last steam locomotive is withdrawn from the road. The time schedule remains as arranged for the steam service, of course, while the steam trains are in operation, but the electric trains can make better time, owing to their advantages in acceleration and control. There have been a few trifling hitches in the electrical operation, owing, principally, to the unfamiliarity of the train crews with the new system, but, on the whole, the success of the Sprague system has been demonstrated. In response to the inquiry of a representative of the Western Electrician, General Manager Hopkins of the South Side company said that the electrical train operation had proved "very satisfactory indeed."

The council of Algona, Ia., is considering granting a franchise to a private concern to put in an electric-light plant, or forming a stock company of local capitalists who will put in such a plant for the city, to be operated in connection with the water-works.

Mayor Truelson of Duluth, Minn., thinks the plant of the Hartman Electric company to be worth only about $100,000, which he would be willing, on the part of the city, to pay for it. He says that if the Hartman company does not care to sell he is in favor of putting in a competing plant and making reasonable rates.

The Trimming and Cleaning of Enclosed Arc Lamps.

By J. H. Hallberg.

The trimming and cleaning of the inner globes of enclosed arc lamps is of the utmost importance, as the efficiency or candle power depends, to a large extent, on the transparency of the inner globe. It is a serious matter and well worthy of careful consideration. I wish to suggest a system for doing this work, which will save many inner globes, "kicks" from customers, carbons and labor. It may be applied to any sized plant.

The following suggestions are based on the claim that one set of 12 by ½ inch solid carbons will burn from 125 to 150 hours and apply to all enclosed arcs except the alternating, in which is used various sizes of carbons, some lamps using one solid and one cored, others two cored carbons, and there may be alternating-current lamps that use solid carbons in both top and bottom, but as yet they are not advertised in this country.

Let us suppose that I am the manager of a lighting plant, and a number of enclosed arcs have been put in service for either commercial or street lighting, and that I am to get up a system of trimming and cleaning these lamps. I would proceed as follows:

First, I would make a box of tin or zinc about 18 inches long by 13 inches wide by six inches high and space it off so I would get room for 12 inner globes, 25 or more upper carbons, 25 or more lower carbons, 25 stubs of carbons left in upper holder after 125 to 150 hours' run, 25 stubs of burned-out lower carbons and one space for a few small repair tools and bolts for wiping.

I would cover the inside (bottom) with one-sixteenth-inch thick asbestos, which will prevent the chipping or breaking of the inner globes when they are placed in their spaces. I would attach a strong strap to this case for carrying, and get an oil-cloth, or something similar, to cover the globes and carbons in rainy weather, as dampness on carbons and inner globes has a bad effect on enclosed arc lamps.

Then I would buy one extra inner globe for each lamp, as many carbons as I would need for one year and a few screws, etc., that are liable to get lost or damaged during burning or trimming. When the time came for retrimming the lamps, I would place 12 clean inner globes in their respective spaces in the box, leaving the thirteenth space empty, 25 upper and 25 lower carbons in their spaces, and a few of the small screws, etc., with tools and cloths in their space. Now all spaces but three in the box are filled. I put on a pair of gloves, pick up my box and ladder and start to trim.

First, shut off the current, then lower outer globe, take out dirty inner globe, place the latter in the thirteenth space in the box, remove carbons left in upper and lower holder, and place them in their respective spaces, place new upper carbon in its holder (firmly) and try it up and down slowly to insure against binding, place new lower carbon in its holder, being sure no broken piece is left in bottom and that carbon is down as far as it should go, put on clean inner globe and lift clutch up so as to see everything works right.

Take a cloth and wipe any part of lamp that may be dusty or dirty and reach down and wipe out the outer globe, as there is always more or less dust accumulated in it, either from the outside or from the arc enclosed in the inner globe. Now I would set the outer globe in its support and wipe it on the outside and turn on the switch. In a properly designed lamp the trimming should not take over three to five minutes. After trimming 12 lamps I would get a fresh supply of inner globes and carbons, leaving the old ones in the station. This would be continued until all my lamps were trimmed.

After trimming I will have a number of burned top and bottom carbons and dirty inner globes. I will first proceed to cut the carbon pieces left in upper holders for the lower holders at the next trimming. I would make a simple gauge of some metal the exact length marked on tag of lamp, and cut my carbons with a hack-saw or a pair of shears, which I prefer, to this gauge, always taking care to get the size within one-sixteenth inch. This exact size is of much importance.

My next move will be to clean the dirty inner globes. In looking them over I will find most of them are covered with a gray-white dust or film on the inside, which comes off if the globe is washed in clean water; but I will also find some that show a brownish stain around the top of the globe which apparently will not come off after they are washed in water, no matter how much it is washed. The most common cause of this is impure carbons, which contain too great a proportion of metallic substances, or it may be caused by the lower carbon being too long, which in turn brings the arc too near the neck of inner globe, or possibly there is too much current flowing across the arc, especially during the few minutes after trimming lamp with new carbons, which causes an excessive flame that gets in contact with the globe and in that way stains it.

There is no new knowledge only one way to clean a globe in this condition and that is by dipping the burned part in hydrofluoric acid. This acid is very dangerous to handle, and much care should be exercised when it is used. As this acid will eat through almost every material except lead and wax, it must be kept in a jar of that material. I prefer lead, as the wood gets worn with it acting on the glass, and I have seen cases where the wax melted and let the acid run out.

I will now construct a round lead vessel about six inches high by 3½ inches in diameter (inside). I would make this out of an ordinary lead pipe about 2½ inches diameter. After cutting it off, I would set it in clay or something similar, and pour melted lead in the bottom so as to form a bottom-side about one-half inch thick. Be sure it makes a good tight joint. You must not solder this bottom as the acid will eat out the solder. Now I will buy one pint of hydrofluoric acid and put enough in this lead vessel so that it will cover all but one-half inch of the inner globe when the latter is inserted. The hydrofluoric acid is put in specially prepared wax bottles and you must be careful when you handle them, especially in very warm places. If you get any acid promptly made with a view to the early resumption of dividends."

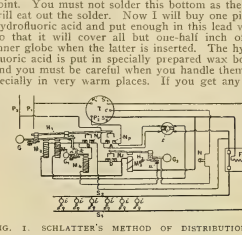

FIG. 1. SCHLATTER'S METHOD OF DISTRIBUTION OF ALTERNATE CURRENTS BY TRANSFORMERS.—PLAN OF CONNECTIONS FOR A SINGLE TRANSFORMER.

on your hands, it is well to wash them in water at once and apply pulverized soda or something similar. It is well to have something of that kind on hand at all times.

I will select a place for this cleaning where I can get a draught to carry off the gas fumes and if possible have constantly running water; if running water cannot be obtained, get two large tubs of clean water and boxes with perforated bottoms spaced off for about 25 globes each.

After selecting the stained globes, I put on a pair of rubber gloves and commence work. First, dip part of globe that is burned in the acid (this will only take about one or two seconds in ordinary cases), then give it a liberal bath in the first tub of water; now we may find a light white film on the globe which we wipe off with a cloth and then dip in the second tub of water. After this place it in the box with the perforated bottom; after your box is full, take it to some warm place, say on top of a radiator, steam-pipe, boiler, etc. After an hour you will find your globes are as good as new, although some may need a little further cleaning with a cloth.

Some people advise, in place of using the acid the way above described, to use 10 parts of water to one part of acid, and place your globes in this bath. This method takes at least 10 minutes, and if several globes are in the bath at once your chance of breakage is greatly increased.

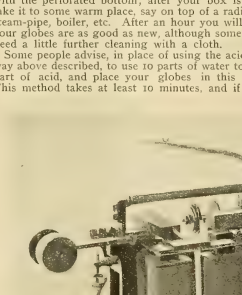

FIG. 3. SCHLATTER'S METHOD OF DISTRIBUTION OF ALTERNATE CURRENTS BY TRANSFORMERS.—PERSPECTIVE OF APPARATUS FOR A SINGLE TRANSFORMER.

General Electric Company.

The statement of the General Electric company for the last year has already been published. At the annual meeting of the stockholders of the company, which was held at Schenectady on May 10th, 210,000 shares were represented. The following directors were elected: Gordon Abbott, Boston; Oliver Ames, Boston; C. A. Coffin, New York; T. Jefferson Coolidge, Jr., Boston; C. H. Coster, New York; Thomas A. Edison, Orange, N. J.; George F. Gardner, Boston; Eugene Griffin, Ardsley Casino; F. S. Hastings, New York; Henry L. Higginson, Boston; J. Pierpont Morgan, New York; Robert Treat Paine, 2d, Boston, and George Foster Peabody of New York.

The following resolution was adopted: "Resolved, That the interests of the stockholders require that any proper or necessary adjustment of the impairment of the capital of the company should be

Schlatter's Method of Distribution of Alternate Currents by Transformers.

In practice, says l'Industrie Electrique, commenting on an article in Polytechnikai Szemle, transformers are seldom employed up to their full capacity. In fact the greater portion of these distributers are exclusively used in illumination, while comparatively few are used on motor circuits. Records of central stations show that the daily work accomplished by these distributers of energy average only about two hours of full-load service. From this data the following table of efficiency was worked out by Ganz & Co.:

Transformer of 10	kilowatts.....	efficiency 0.75
Transformer of 5	kilowatts.....	efficiency 0.692
Transformer of 2.5	kilowatts.....	efficiency 0.652
Transformer of 1	kilowatt	efficiency 0.515

Among the methods suggested for reducing the waste of current is the Schlatter method of cutting out the idle transformers. The apparatus employed is designed for single transformers or for a battery of them.

Figs. 1 and 3 represent the first form. P1 and P2 are the primary conductors, S1 and S2 secondary conductors, T the transformer and t a small auxiliary transformer of which the primary and secondary windings are in series with the corresponding windings of the transformer T. M1, M2 and M3 are the electromagnets, which, having different windings, have consequently different self-inductions. The armatures of these electromagnets are fixed on levers H1 and H2, which also support the forked links which dip in the mercury cups A, B and D, while n k is an escapement, G, G1, G2 are counter-weights, N is an incandescent lamp in circuit with the magnet M4, c is an intermediate terminal on the transformer T, say of 50 volts, and F is the meter shunt. The lamps and other apparatus fed are represented by i.

The transformer is not completely cut off when idle, but the combinations effects a reduction of about 95 per cent. of the loss, because of the almost complete transfer of this to the smaller transformer t. For this purpose the latter has but a small primary winding, so that the greater portion of the waste is absorbed by the auxiliary transformer. If a lamp i is put in circuit, the two transformers, T and t, being in series, will furnish the necessary current, which will pass through M1, energizing it and tip the lever H1. The forks will drop into the mercury cups, completing the circuit from t through its primary via A, and through its secondary and M1 via B. T is now in service, and H1 remains held down by M2, this last being energized by the current feeding the lamps i, and is only restored to its normal condition of repose when this current is cut off. The track of this secondary current is as follows: t S2 i S1 T M3 M1 t, when idle, and when under a load T S1 i S2 B M2 M3 T.

The apparatus with some modifications is equally applicable to a battery of transformers. This arrangement includes electromagnets capable of drawing down their respective armature levers with any current for which they are adjusted, and thus adding a new transformer to those already in action.

This process seemed feasible enough, but experience showed that when the first lever was tipped the second transformer was placed in branch circuit, and consequently each transformer delivered a certain amount of current; the first lever then commenced a series of vibrations, which, in addition to wearing out the apparatus, had a weakening and fluctuating result on the candle power of the lamps on the secondary. To remedy this defect a glass tube inclosing mercury has been attached to the lever over the center of motion, which retards this latter, and when the lever is fully open holds it in that position.

New York Electrical Society.

The 187th meeting of the New York Electrical society was an important event in the history of that organization. It was held at Concert Hall, Madison Square Garden, on Thursday evening, May 12th, in conjunction with the electrical exhibition. The society added 103 names to its list of members, including some notable men of the metropolis. Most of the new members are residents of New York, but there were many outsiders admitted. Following is the list:

Ernest B. Laclain, C. C. Bohn, W. G. Ames, E. M. Saules, Frank A. Wunder, Albin Gustafson, Charles J. Klein, Chester Bayles, James Jones, Jr., F. W. Becker, D. Levy, Richard M. Beard, E. A. Quick, Reinhold H. Wappler, Edward Hyans, George M. Loos, P. H. Klein, E. R. French, J. B. Sayles, James H. Spencer, J. D. Gould, Charles A. Hanson, C. W. Price, Lucien W. Jenney, P. M. Mourey, Walter S. Levin, Benjamin O. Ellis, H. D. C. Richards, C. B. Sterling, D. S. Holcomb, Charles E. Dressler, M. C. Rorty, Charles W. Hoffman, Willard S. Bennett, Charles Fred, Many Fred, A. H. Mustard, Harold A. Tileston, Oscar F. Ehrle, William Aus, Elias E. Ries, W. J. Newton, John Burry, Thomas S. Jamieson, S. Clark Harris, R. J. Halligan, V. J. Mayo, T. W. Kloman, Warren A. Brown, Harry Hilbert Conner, Hugo Gotfreund, A. S. Brown, J. Henry Gill, Daniel Von Wien, M. Cushner, John Jacob Astor, Mortimer Norden, Chauncey M. Depew, L. W. Hildberg, Samuel B. Brewster, George Pugh, Emil Finger, Joseph Solot, Charles Penina, Francis Gans, Gottfried Gans, Howard D. Black, William Wilson, Lighthipe, W. M. Logan, Joseph B. Curran, Jr., E. R. Esmond, John McLean, Frank W. Hawley, Cyrus O. Baker, A. O. Schoonmaker, W. C. Burton, R. Hoyt and J. E. McConnell of New York.

H. Krantz, Joseph Albaum, Solomon S. Sugar,

M. J. Wightman, New Brighton, S. I.

The society received many congratulations upon this evidence of prosperity and the evident appreciation that was shown for its work.

Dr. S. S. Wheeler, the president of the society, delivered an interesting lecture upon "Electrically Driven Machinery," which was profusely illustrated. The address was of a popular character, and in the course of his remarks Dr. Wheeler said:

It is evident, from the rapidity with which electric motors have been introduced, that their advantage must be very marked.

First, they are capable of direct connection to the machinery to be operated, which means that their power, however great it may be and however large the machine, can be transmitted by the shaft instead of requiring a cumbersome belt and a pulley on the driven machine large enough to receive by the friction of the belt traveling upon it the needed power. As 1,000 feet of belting one inch wide must pass around a pulley in a minute to transmit one horse power, it is evident that the handling of 100 horse power will require a large pulley and a heavy belt, which is not only inconvenient and sometimes dangerous, but occupies considerable floor space and requires that the machine be heavy enough in design to support the large pulley and the strain of the belt.

Second, motors are capable of regulation and control of their speed and driving power with great convenience, so that electrically driven machines can be started, stopped, reversed or speeded up by the use of small instruments known generally as "regulators," which may be placed close to the machine or in any other convenient location, while machinery driven by belting can be merely started or stopped and then only with a considerable manual effort in shifting the belt, or can be run at other speeds only by bodily removing the belt to a driving pulley of different size.

Third, motors, when used for driving machinery, are usually attached directly to the machine, and being much less bulky than other means of driving, the entire machine is independent of any line shafting, and therefore may be located in a convenient position without regard to this limitation, and in many cases can even be picked up and shifted from one place to another, as the exigencies of work require.

Fourth, electricity permits the saving of one half to two-thirds the power otherwise required. This results from the fact that when the tool is stopped the motor is stopped and draws no power, whereas, in belt-driving, when the tool is stopped the belt or one of the belts is simply shifted and continues to run on an idle pulley.

And last, electricity presents an enormous advantage in the transmission of power.

Electrical Equipment for the Conkey Printing Establishment.

The contracts for the electrical and mechanical plant for the printing establishment of the W. B. Conkey company in Hammond, Ind., have been let as follows:

Boilers.—Standard Boiler company, Chicago. (Two water-tube boilers of a steaming capacity of about 175 horse power will be installed.)

Engine.—Atlas Engine Works, Indianapolis. (One Corliss engine of 150 horse power.)

Generator.—Siemens & Halske Electric company, Chicago. (The generator will be a 220-volt, 100 kilowatt, direct-current machine, directly connected to the engine. The Arnold system of connection between engine and dynamo will be used.)

Motors.—Sprague Electric company, New York. (No less than 72 motors will be required, ranging from ½ to 25 horse power. About 40 motors will be direct-connected to printing presses.)

Heating system.—B. F. Sturtevant company, Boston.

The Conkey company is a Chicago concern, but will have its plant at Hammond. The new building will be 400 feet square and will cover an area of nearly two acres. It will be only one story high, and with especially arranged skylights the whole interior of the large building will be literally "as light as day." All the machinery in the plant will be electrically driven, and the smaller machines will be arranged in groups, with one motor for each. The power and heating plant will be housed in a separate building. The lights and motors will be wired on the same circuits, and 220-volt lamps will be used. B. J. Arnold is the electrical engineer.

Electrocution in Ohio.

Cincinnati, O., May 14.—The electrocution of Frank Early, the Cincinnati wife murderer, in the Ohio penitentiary early this morning, was a horrible spectacle. Early was the first negro to die in the electric chair. Warden Coffin had his misgivings and a couple of hours before the final scene the prison barber was sent to the death chamber with orders to shave the top of Early's head, so as to allow no interference with the electric current. To this operation Early quietly submitted.

When the fatal moment arrived he walked to the chair without support. Two minutes after he sat down all but his head was made fast, the sponge and death mask were fitted, and at 12.15 the hum of the apparatus told that the current had struck him. Three times a current of 1,000 volts was shot through the prisoner. The doctors pronounced him dead at 12.17.

The straps were half removed, when the giant chest moved and groan after groan came from the foaming mouth. "He is dead," said the doctors. "He is not dead," shouted somebody else. Warden Coffin ordered the negro strapped again, and again the body stood rigid under the current. A deep groan answered this shock. Another shock and smoke rose from the right ankle. The third shock at 12.21 was not answered, and so with six shocks and seven distinct groans Early was dead 330 seconds after the first current entered his body. After the body was laid in the corner the doctors wanted to hold a post-mortem examination to see whether the man had died from the first shock, but the relatives would not permit it.

International Electrical Notes.

Russia.—It will be necessary to make a very strong effort to gain a foothold, as the prospects are encouraging. The Russian market is just beginning to show a demand for electrical apparatus, and it will soon develop into a vast field for trade, with which the home industry will not be able to cope.

The municipality of Warsaw is prepared to receive tenders for supplying the town with electric power for lighting and street-railway work.

Australia.—During the last session of Parliament in South Australia an act was passed in favor of the South Australian Electric Light and Motive Power company, which gave to the company practically a monopoly of the electric-light and motive-power business throughout the colony. One of the promoters of the bill was Mr. W. W. Crawford, the representative in Australia of Johnson & Phillips, to whom orders for the Port Adelaide plant have already been transmitted.

Japan.—A water power and electric-light company has been projected by Messrs. Konishi and Shimanoo and other gentlemen in Settsu, the scheme being to utilize a waterfall in Arima of the same province. The object of the company is to introduce electric lighting into the neighboring towns of Nada, Mikage, Nishinomiya, Itami and Amagasaki, and at the same time to build an electric railway between Arima and Mikage.

Sweden.—About 160 kilometers (99 miles) from the Swedish capital there is situated the celebrated waterfall of Elfkarleby, which is the property of

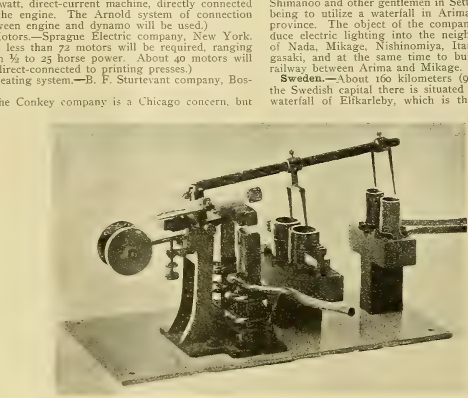

FIG. 4. SCHLATTER'S METHOD OF DISTRIBUTION OF ALTERNATE CURRENTS BY TRANSFORMERS —PERSPECTIVE OF APPARATUS FOR A BATTERY OF TRANSFORMERS.

the government and, at an average height of water, represents about 100,000 horse power. For a long time it has been planned to utilize this enormous power for Stockholm, and during the last few months practical steps have been taken by the government toward the scheme. Engineers have been ordered to thoroughly examine the conditions of the fall and draw up the plans. It is proposed to utilize 20,000 horse power. The total expenditure will amount to about $2,160,000. Orders for the machinery and supplies involved will be forthcoming at an early date, and American manufacturers should avail themselves of this opportunity.

South Africa.—An electric-lighting installation is under contemplation for the Monastery diamond mine, Orange Free State.

The provision of an electric-light installation for Woodstock, Cape Colony, is under consideration by the Town Council.

The proposed electric-lighting plant for East London will include 43 2,000 candle power arc lamps, 327 32 candle power incandescent lamps, 2,304 16 candle power incandescent lamps, five continuous-current machines for arc lighting, three direct-coupled alternators for the incandescent service, two switchboards and the usual supplies.

The decision of the directors of the Angelo-Driefontein mines to increase the mill power to 400 stamps will necessitate the installation of additional machinery.

H. L. G.

The building inspector of St. Paul has completed plans for the proposed electric-light plant, and estimates its cost at $200,000. The city clerk will probably take bids on the plans.

The electricians of Winona, Minn., have formed an organization, with H. B. Kline as president, M. McAllister as vice president, John McIne as secretary and Frank Wood treasurer. Meetings will be held every Saturday night.

The police of Des Moines have discovered about $100 worth of electric light fixtures in the possession of E. Gordon. The fixtures were stolen from the Capital City Electric Light company.

TELEPHONE, MAIN 1746.

Eastern Office: 809 Postal Telegraph Bldg., New York.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome, and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—the only general electrical paper published in the West—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

The principal event of the year in electrical circles is at hand. It is the annual meeting of the National Electric Light association, which will be held in Chicago on June 7th, 8th and 9th. The preparations for this convention are now far enough advanced to warrant the statements that it will be truly representative in character and that it will be attended by a larger number of central-station men than any previous gathering of the organization. The gentlemen in charge of the arrangements for the meeting have received personal assurances which warrant them in making these assertions.

But there are other reasons for anticipating a well-attended, instructive and profitable meeting. The general condition of the industry shows marked improvement, the electric-lighting companies of the country are in much better condition financially than they have been for several years, the association is stronger in membership and better organized than formerly and the inducements held out by Chicago are superior to those of any other city in the country for practical men. The local electrical interests are engaged in making arrangements for the entertainment of the members that will be thoroughly enjoyable, but will not interfere with the work of the convention.

The programme for the meeting includes several papers on subjects of interest to every central-station manager. There will also be a general discussion of several topics which are announced elsewhere in this issue. It was deemed advisable to present fewer papers than heretofore and have them properly discussed. Every practical man recognizes the value of open discussion, and it is hoped that the Chicago meeting will mark a turning point in the history of the National Electric Light association by establishing the rule of thoroughly discussing every paper that is presented. There is no doubt that the papers will contain much matter for discussion. The list of topics and names of the writers alone should ensure an interesting and successful meeting.

The London Electrical Engineer refers to Electrical Engineering of Chicago as "an American contemporary, at one time a staunch supporter of the independent telephone companies." It is evident that the self-appointed champion of the Bell interests has not made much of an impression abroad.

With some modifications the automatic telephone system with which American telephone managers are familiar is being introduced in England. At the present time, however, it would seem to be difficult to successfully introduce an independent system in England. The National company is in disfavor, but there appears to be no inclination on the part of the local authorities to encourage competition. In fact, the government discourages the establishment of competing corporations, and the general opinion seems to be that the solution will be found in the establishment of a telephone department in the Postoffice, which will control all the telephone business of the country. This ought to be fully in accord with English ideas, and will probably be satisfactory to the National company if it can get its price for the present equipment.

Industrial exhibitions have become so common that there is little in the way of novelty to be expected from them; indeed several of those that have been conducted of late follow the same general plan. This may be explained by the fact that these exhibitions were of a local character, and while many of them took on an air of importance and paraded under high sounding titles, their scope and character were limited. It is proposed now to start on an entirely new plan, and the committee on interstate and foreign commerce has recommended the passage of a bill by Congress to authorize and encourage the holding of a national exposition of American products and manufactures especially suited for export at Philadelphia in 1899. This exposition is to be held under the auspices of the Philadelphia Commercial Museum, which is a public institution, receiving financial support from the City Councils of Philadelphia and the state of Pennsylvania. This organization is devoted in a large measure to assisting in the development of foreign trade, and as its agents are in close touch with the foreign market, they should certainly be well qualified to hold such an exhibition.

The Eastern Extension, Australasia and China Telegraph company is an English corporation. It owns the submarine cable line between Hongkong and Manila, which was cut by Admiral Dewey after the naval battle in which the Spanish fleet was destroyed and the fortifications of the bay reduced. The last report of the directors of the company for the half year ended December 31st, which has just been given out, mentions the fact that direct cable communication with Manila had been established. The report says: "The contract made with the Spanish government for extending the company's system from Manila to the islands of Panay, Negros and Cebu was successfully completed and the new cables opened for traffic in November last. Since the close of the half year a further contract has been entered into with the Spanish government for improving telegraphic communication with the Philippines by extending the Hongkong cable, which was originally landed at Cape Bolinao (Luzon), direct to Manila. The contract was completed last month, and the station at Bolinao removed to Manila." Since the work just mentioned was completed the comparatively insignificant cable line to Manila assumed considerable importance. It was not thought when the extension was undertaken that the Manila cable was destined to become such an important factor in the affairs of Europe and America.

Several important points of law affecting the rights and obligations of electrical construction and central-station companies were elucidated by the Court of Appeals of Texas recently in passing upon the case of the A. J. Anderson company against the Cleburn Water, Ice and Lighting company. Action had been instituted to recover the contract price of an electric-light plant, alleged to have been erected in compliance with a written contract. The case had been once before considered by the Court of Civil Appeals and sent back to the trial court for rehearing. In the opinion accompanying the second review of the case the court declares that if a construction company fail to construct a plant in substantial compliance with the terms of the contract, and the central-station company refuse to accept it in an incomplete state, and by reason of the former's default the latter be damaged, the latter can recover as damages the difference between the value of the plant, if completed in accordance with the terms of the contract, and the price agreed to be paid by the contract. If there had been a delivery and an acceptance of the plant in an incomplete condition, then, the court holds, the measure of damages of the company that ordered the plant would be the difference in the value of the plant actually constructed and the value of the plant if constructed in accordance with the terms of the contract. Again, if the construction company fail to furnish and wire certain lamps in accordance with the terms of the contract, and the other company accept the plant in such incomplete condition, the court holds that the latter company is entitled to have considered as a proper basis for damages that it was to have received the sum paid by the persons having the use of such lamps, or the sum of $2.50 per light, and that it is not necessary to set out the names of all the persons from each of whom that sum would have been received if the lamps had been wired in. The court further declares that when a contract provides that the acceptance of an electric light plant shall be subject to the approval of a certain named electrician, and when the company constructing the plant makes an effort in good faith to get that electrician to examine it, that provision of the contract will be substantially complied with; but that where the company does not in good faith make an effort to secure such examination of the plant by the electrician specified, and it is not examined by him, that will constitute a complete defense to a suit by the construction company on the contract.

WAR NEWS.

Battleship Detecting Approach of Torpedo Boat by Searchlight.—Nearly every American of average intelligence must have gained at least a superficial knowledge of the methods of modern naval warfare by the quickening influence of the present war. It will be sufficient, therefore, to merely indicate the value of the searchlight in the defense of large warships from torpedo-boat attack at night, to appreciate Mr. Lee's fine drawing, which is herewith reproduced from Collier's Weekly. When it is considered that a battleship may be attacked by several 25 or 28-knot torpedo boats at once; that the boats may come from several points of the compass at the same instant; that any one of them, by getting within torpedo range of the object of attack, may launch a missle of destruction that will literally blow the ship out of water, and that all this is done "Under Cover of Night," as Mr. Lee entitles his picture—the paramount importance of the fierce, searching beams of the electric projectors of the great ship is at once apparent. But once the on-rushing boat is "picked up" by the searchlight it is doomed. It will be almost inevitably riddled and sunk by the storm of steel projectiles from the battleship; and the projector will have demonstrated its useiulness.

Cable Cutting at Cienfuegos.—On May 11th the cruisers Nashville and Marblehead, which have been doing blockade duty on the southern coast of Cuba, were ordered to Cienfuegos, with the revenue cutter Windom, to cut the cables there, this being part of the plan to isolate the Spanish forces on the island from the rest of the world. The map published in the Western Electrician of April 16th shows that three cables land at Cienfuegos, all connecting with other ports on the southern coast of Cuba. One goes west to Batabano, another east to Manzanillo, and the third, the most important of all, is a duplicate cable to Santiago, where it connect with the direct cable to Jamaica and also with that to Hayti by way of Guantanamo, thus giving communication with Europe. Two of the cables were cut, but the Americans were forced to retire under a heavy fire from the shore before finishing their task, and the third cable remained intact. It is said that this is the eastern inshore cable leading to Manzanillo. If the land line between Manzanillo and Santiago is open to the Spaniards, General Blanco can still telegraph from Havana to Madrid.

The cable-cutting expedition consisted of volunteers in four boats (two steam launches and two cutters), protected by the guns of the Nashville and Marblehead. The boat party consisted of men with grappling irons and cable-cutting tools, sailors at the oars in the cutters and a guard of marines. The official report states that the men performed their work with the utmost coolness and intrepidity under the fire from the infantry and Maxim guns on shore. The Spanish soldiers were sheltered in rifle pits and masked batteries, but must have sustained considerable loss from the fire of the ships and boats. The American loss was two men killed and seven wounded. Lieut. Winslow was slightly wounded.

Other Cable News.—It has been asserted that the French cable company delayed for 24 hours an important dispatch to Washington from Captain Cotton of the United States auxiliary cruiser Harvard at St. Pierre, Martinique. But the truth of the assertion is denied by the manager of the company in Martinique, who makes this statement: "Captain Cotton presented himself at the office of the company at St. Pierre and asked by what cable line messages were transmitted to Washington. When he was informed that such messages went by way of Fort de France and Hayti he refused to give us his dispatch, because a Spanish torpedo boat was at that moment at Fort de France. Not taking into account professional secrecy, he told the American consul in the presence of M. La Lung, under these circumstances he preferred to give his dispatches to the English company, in spite of the delay of 24 hours which they have to submit to on account of accumulation of business on the lines of that company. I protest against the statements made, as we leave our office open to midnight or one o'clock in the morning when necessary, while the West India company closes at six o'clock in the evening, local time, and also because we do everything possible to be agreeable to the American government, forwarding its messages very rapidly, when we have any." The United States consul partly corroborates the manager's statement.

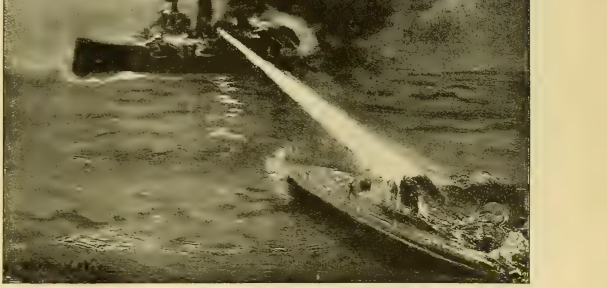
On Sunday it was asserted in New York that the North Atlantic cables were to come under the government censorship, the telegraph companies having received instructions to send by cable no message pertaining to the movements of American men of war which would in any way give the outside world information of contemplated naval operations. But two days later the Anglo-American Telegraph company issued the following notice: "Pending further decision by the chief signal officer, we will accept press messages without restrictions." A still later dispatch states that a censorship has been practically established.

The Mediterranean cable is still interrupted.

The cable between St. Lucia and St. Vincent, in the West Indies, was interrupted for a few days, cutting off telegraphic communication with St. Vincent, Barbadoes, Grenada, Trinidad and British Guiana. This interruption was thought to have been possibly caused by the Spanish fleet off Venezuela, but was probably due to one of the many accidents which befall ocean cables.

Electricians Drowned in New York Bay.—The French liner La Touraine, outward bound, through the main channel off Sandy Hook point, on Saturday last, upset a surl boat containing eight men, who were engaged in laying submarine mines. Two electricians were drowned and two more were severely hurt. The other four were picked up by a patrol tug and landed at Fort Wadsworth. The two who had been injured were taken to Sandy Hook. The government employes and members of the engineer corps blamed the pilot of the French liner.

About the time the steamer left her pier Lieut. Robert McGregor, Corps of Engineers, U. S. A., stationed at Sandy Hook in charge of the mine fields, had sent out three boats' crews from the battalion of engineers to replace two or three groups of observation mines that had been carried away just off the Hook by passing steamships. When the boats were sent out patrol tugs were ordered to warn approaching vessels away from the small boats. A few minutes after 12 one of them, the Atwood, sighted La Touraine coming down the main channel. As soon as the Atwood sighted the liner the tug signaled to the pilot to keep close to the white buoys, because boats were mining the channel just off the Hook. The pilot of the liner said he endeavored to follow the instructions, and thought he had done so, but in navigating the narrow channel he fouled the cable and upset the boat. It seems that the men at work in the small boat had the cable lifted across the bow of the boat. They were attaching a junction box to it when the steamer came along. The tug William McKinley was in the channel, and to avoid her La Touraine sheered to the right, and in sheering fouled the cable and upset the small boat. Of the eight men in her, two clung to the box on which they were at work. They went down and did not reappear, both of them being drowned. The men who were drowned were Victor Pessa, an electrician who lived in Brooklyn, and Robert Middleton, an employe of the General Electric company, who resided in Orange.



BATTLESHIP DETECTING APPROACH OF TORPEDO BOAT BY SEARCHLIGHT.

Wonderful Expansion of Wireless Telegraphy Proposed.—The following communication, appearing in the Pall Mall Gazette of London, was apparently written in good faith: "In these stirring times of war, it has become more patent than ever how important it is for this country to be in uninterrupted telegraphic communication with its numerous colonies and dependencies. The mere possibility of the cables between Cuba and the outer world being cut naturally suggests what is in store for this country should it unfortunately be at war with a first-class power. I am surprised that a proposal made by Prof. Silvanus Thompson, in his recent lecture on 'Telegraphy Across Space' at the Society of Arts, has not created the attention it deserves, coming, as it does, from so high an authority. The proposal was, that if £10,000 were put at his disposal for the purpose, he would be able to erect the necessary apparatus for telegraphing without wires intervening between this country and any part of the globe. To be able to telegraph from London to Cape Town or to Calcutta, or to any where you like, without the possibility of the wires being cut, for the simple reason that under Prof Thompson's plan there would be none to cut, is certainly a consummation devoutly to be wished.' I suggest that Prof. Thompson's plan be further examined, and if he can substantiate his claim—as from his great reputation there should be little doubt—the necessary funds should be put at his disposal by government, in order to enable him to complete his experiments and to bring to perfection his plan of telegraphing across space." Prof. Thompson's remarkable offer is said by the London Electrical Review to have been a "passing remark."

The Signal Service.—Lieut. Samuel Reber, U. S. A., chief signal officer of the Department of the Gulf, has been ordered to report to General Shafter at Tampa, and has left Atlanta for that purpose. Lieutenant Reber has many friends among electrical men, as he has devoted much time to electrical study and experiment. He was one of the judges of the Department of Electricity at the World's Fair.

Captain R. E. Thompson, of the United States Signal Corps, passed through Chicago early in the week on his way to San Francisco, having been detailed to take charge of the government electrical work, in connction with cables and army and navy signaling in the Philippines.

Periodic rumors of the approach of Spanish warships have disturbed some nervous people along the New England coast. However, the signal service is very well established and the actual near approach of a foe seems impossible without ample warning being given.

Miscellaneous Notes.—Manager Naylor, of the electric light plant in Wadena, Minn., has placed red and blue electric lamps on top of the water-tank to give notice of the way battles have gone in the war. If Spain is winner the red lamps will be turned on; if the United States is on top, the blue will announce the glad news.

Throughout Spain there are a number of electric-light enterprises worked by British capital, and in fact having head offices in London, and among these is the Malaga Electricity company. The difficulty of obtaining fuel supplies, owing to coal being contraband, necessitates the closing down of the company's works. This has led to correspondence between the directors and the British Foreign Office as to whether steamers could be chartered from England to carry coal to Spain for purely commercial purposes. The reply from the Foreign Office (which, as the London Electrician says, is very diplomatic) is as follows: "I am directed by the secretary of state for foreign affairs to acknowledge receipt of your letter inquiring whether, in the circumstances stated therein, you may charter two Steamers from this country to convey coal to Bilbao and Malaga. In reply, I am to state to you that his lordship regrets that he cannot offer any advice on such questions. In time of war commercial transactions must be conducted at the expense solely of those interested in them who can obtain, if necessary, such legal advice as it would be open to them to take in other important matters. I am to add that to give official advice in such matters would be a departure from the course which has been pursued by this department in the case of former wars."

W. J. Gray & Co. of Minneapolis will furnish an estimate of cost for putting in an electric-light plant for Madison, Minn.

DEVELOPMENT OF THE TELEPHONE FIELD.

Protecting Telephone Circuits from Heavy Currents.

Lightning is not the only destructive agent against which the telephone manager must constantly guard, as heavy currents for power and lighting service are equally dangerous. The device illustrated in the accompanying cuts is intended to protect telephone switchboards from heavy currents of all kinds and it is designed to automatically cut out the telephone line before a point of danger is reached. It is not necessary to impress upon experienced exchange managers the necessity of adopting some method of protection. Fig. 1 shows the general form of an arrester of 100 lines, with the spring in the center, A A. Fig. 2 is a cross-section of the spring, electromagnet, armature, etc., and Fig. 3 shows the cross-section of Fig. 1.

The practical operation of the device may be explained as follows: The lines come from the cable terminals inside of the office to the cross-connection board, through the two binding-posts, along the automatic spring, over the ground strip, which is insulated from the springs, and through the one-fourth-ampere mica fuses to the switchboard. When a heavy current comes in on any line, it will, of course, seek a ground through the path of

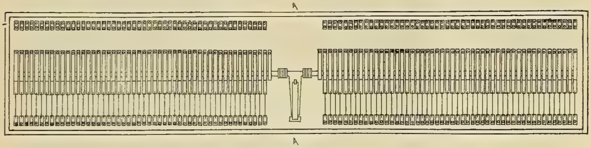


Fig. 1. One-hundred Line Automatic Lightning Arrester.

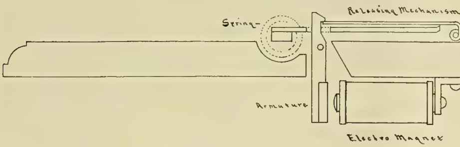

Fig. 2. Cross section at AA.

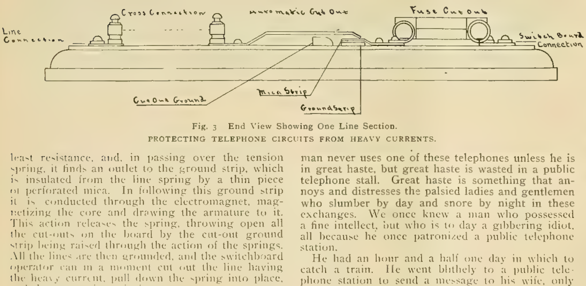

Fig. 3. End View Showing One Line Section.

PROTECTING TELEPHONE CIRCUITS FROM HEAVY CURRENTS.

least resistance, and, in passing over the tension spring, it finds an outlet to the ground strip, which is insulated from the line spring by a thin piece of perforated mica. In following this ground strip it is conducted through the electromagnet, magnetizing the core and drawing the armature to it. This action releases the spring, throwing open all the cut-outs on the board by the cut-out ground strip being raised through the action of the springs. All the lines are then grounded, and the switchboard operator can in a moment cut out the line having the heavy current, pull down the spring into place, and the system is again in service.

If the operator should notice a fluttering of the drops, indicating the presence of a heavy current, the pressure of a button provided on the switchboard will throw a battery current into the electromagnet and open the arrester. With a device of this kind it is claimed to be impossible for heavy currents to burn out switchboard apparatus.

Another excellent feature of the device is its quieting effect on the line, taking off the induction and noises through the proximity of the line to the ground strip. This automatic arrester has been in service for about a year, and its usefulness has been demonstrated on many occasions in saving switchboards from absolute destruction. It is made by the Keystone Telephone company of Pittsburg.

Crossing of Telephone and Trolley Wires.

A serious fire is reported to have taken place in the Zurich telephone exchange, as a result of a telephone wire falling across a trolley line. The accident caused a jet of flame to shoot out of a spring jack as the operator was making a connection. Simultaneously at different parts of the switchboard this experience was repeated, and in an instant the whole wooden board was on fire, and the operators had barely time to escape. One girl received a shock which threw her to the ground. Although the fire was extinguished in two hours, the whole exchange was completely burnt out. Several accidents have recently occurred in Switzerland through telephone wires falling upon traction conductors. In Geneva and in Basle two men were killed from this cause, and near Gersau, on the Vierwaldstätter See, a wood was set on fire by a contact between telephone and trolley wires, and two men who were assisting in extinguishing it received fatal shocks.

Public Telephones in Greater New York.

Anybody who has ever given up 15 cents for the privilege of swearing four or five hours into a public telephone, with an instrument of torture more terrible than the iron boot glued fast to his ear, will be delighted to learn that the telephone companies have concluded to raise the tariff on this sweet privilege to 25 cents a throw, says the New York Telegram. There is probably nothing on earth so grateful and comforting as sending a message through a public telephone station in Greater New York. A man never uses one of these telephones unless he is in great haste, but great haste is wasted in a public telephone stall. Great haste is something that annoys and distresses the palsied ladies and gentlemen who slumber by day and snore by night in these exchanges. We once knew a man who possessed a fine intellect, but who is to day a gibbering idiot, all because he once patronized a public telephone station.

He had an hour and a half one day in which to catch a train. He went blithely to a public telephone station to send a message to his wife, only five blocks away. He gave the password to the attendant, and shut himself up in the stall. He placed the receiver to his ear and waited. Then he waited some more. Then he rang the bell and said "please." Then he rang the bell again and courteously inquired what in the name of Gen. Blanco and his band of black-hearted pirates was the matter. A courteous voice answered and said: "I—sss -33 w—!! !!333—boom rah!!"

This information, while valuable, didn't satisfy the gentleman, so he took hold of the bell handle and twirled it until his arms ached and his eyes bulged out and his tongue cleaved to the roof of the house. Then he yelled into the machine again and asked a question that we cannot find room for in this column. Just at that instant somebody blew up the battleship Maine and a train of cars ran off a high trestle, and by some happy chance the noise of the double catastrophe was instantly transmitted to the patient gentleman's ear. The shock so pleased and delighted him that he tore the receiver out by the roots and kicked a hole through the side of the building and knocked out a side of the boxstall and set the house on fire with red, white and green cuss words. When he finally reached the street and ran shrieking to the station he found his train had been gone a couple of hours, and then he fell in a fit and was carried away to a padded cell. By all means let the telephone rates be raised—let them be raised high enough to prevent such awful tragedies as this.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Iowa and Nebraska Telephone company, with headquarters at Spirit Lake, Ia., has bought the Cherokee, Ia., Telephone company, which owns exchanges at Spirit Lake, Sibley, Sheldon and Wayne, Neb.

The local telephone exchange for New Richmond, Wis., is to be put in at once. A. T. Presson of Hudson is the owner.

The ordinance and resolution committee of the Duluth, Minn., council reported against regulating telephone rates, in view of the opinion of the city attorney. It sets forth that rates should be as low as named in the proposed ordinance, and recommends that the city should either get such rates on granting a new franchise or should construct a system of its own.

The Watertown Telephone company of Watertown, S. D., has put in new receivers and transmitters, which have greatly improved the service.

The Atlantic-Corning Telephone company has completed a line between Atlantic and Corning, Ia. The wire will probably be leased to the Mutual Telephone company, which is now endeavoring to secure a franchise in Atlantic.

F. L. Cliff of Ortonville, Minn., has been granted a franchise for a local exchange at Wheaton, Minn. It will connect with the Minnesota Central Telephone company's wires.

The Northwestern Telephone Exchange company, whose men were arrested in Minneapolis, while setting poles on Lake street, holds that Lake street is a post road. Furthermore, it had a large crew of men idle, waiting for permission to set the poles, which had been promised but failed to come, and finally took matters into its own hands to force a decision.

The Western Electric Telephone company will extend its toll wires to Howard, S. D., and probably to Canova, S. D.

The Minnesota Mutual Telephone and Telegraph company is soliciting subscriptions to build a line along the St. Paul and Duluth railway from Rush City, Minn., to St. Paul.

The Northwestern Telephone Exchange company is securing a right-of-way into Madison, S. D., by condemnation proceedings. This company has begun proceedings for a right-of-way between Hutchinson, Minn., and Glencoe. The same company has also begun work on a toll line from Anoka to Cambridge, Minn., via St. Francis.

The Nicollet County Telephone and Telegraph company of New Sweden, Minn., has been incorporated to build a telephone line from Winthrop, Minn., to St. Peter.

The Perry Telephone company has material ordered for the new exchange to be put in at Adel, Ia. The Iowa Telephone company has now made application for a 20-year franchise at Adel and offers to bear all expenses involved in granting the franchise.

The Jefferson Telephone company has moved its exchange to new quarters in Jefferson, Ia.

The Union Telephone company has put in a new 100-drop switchboard at Boscobel, Wis.

The Cedar Valley Telephone company has completed connection with Finchford, Winslow and Boies, Ia.

The Iowa Telephone company has been soliciting subscribers at Elkader, Ia., for an exchange.

The Pierce County Telephone company of Ellsworth, Wis., and the Hudson Electric Exchange company of Hudson, Wis., are arranging to extend toll lines to the Twin Cities. This will give connection with a great many of the smaller towns near the western boundary of Wisconsin.

The Mississippi Valley Telephone company has begun work in Minneapolis, in order to protect its bond, by dressing poles and supplying them with crossbars. The company expects to have its system in working order by January 1st.

The Wisconsin Telephone company is pushing work on its toll lines in northwestern Wisconsin and expects to have connection between Ashland and Stevens Point, Eau Claire and other points by July 1st.

A telephone line will be built to connect Galesburg, Hillsboro, Blanchard and Clifford, Wis.

The Dakota Central Telephone company of Aberdeen, S. D., has connection with 52 towns now and expects to be connected with 100 towns by July 1st.

The annual meeting of the La Crosse Telephone company was held in La Crosse, Wis. The company has 631 subscribers, a net gain of 113 in the past year.

The Marshfield telephone exchange will be established at Marshfield, Wis., at once.

The Northeastern Telephone company has been incorporated at Rush City, Minn., with $50,000 capital stock. Connection will be made with the Twin Cities, via Stillwater.

The Rocky Mountain Bell Telephone company

will construct a line from Missoula, Mont., to Wallace, Idaho, as soon as the weather will permit.

The Spokane and British Columbia Telephone company has completed long-distance connection with Republic.

Automatic Telephony in England.

Promoters of the automatic telephone system, which has been developed in this country during the last few years, have succeeded in attracting English capitalists and forming the Direct Telephone Exchange Syndicate of London. The English corporation is introducing two distinct systems, one for exchanges of less than 400 subscribers and one for those having a greater number of instruments connected. It is explained that there must be one automatic switch for each subscriber in any case, and in exchanges to which not more than 400 subscribers are connected their lines are "multipled" to each subscriber's switch. In larger automatic exchanges there are two automatic switches per subscriber, one being a junction-wire switch, for it would not be feasible to multiple every subscriber's line at each switch.

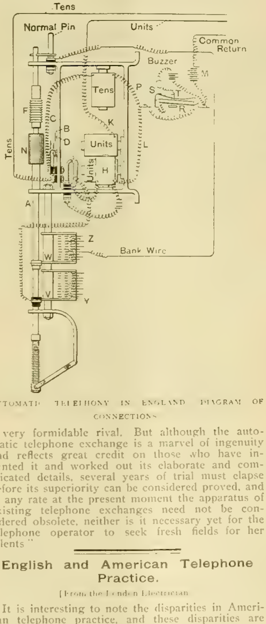
In a 100-subscriber system the numbers are from 101 to 199. Two lines are necessary for each subscriber to the exchange, and in addition either an earth return or, preferably, a return wire common to all the subscribers. The two lines are called for distinction the units line and tens line. The first movement of the disk on the subscribers' instrument connects the units line once to the common return, the second movement sends a number of similar current impulses through the tens line, and the third movement sends currents to the units line again. The first current flows from the battery M in the exchange (see cut), through the wire L, and the electromagnet marked "Units," to the units line by way of the wire K. At the subscriber's instrument it passes to the common return, and comes back through the latter to the battery M. The units electromagnet causes the toothed cylinder N, which is fixed to the shaft A, to rotate one tooth; it then throws two pawls into engagement with A to prevent it from turning further until the armature is again attracted, and finally it moves the spring B over to C and away from the contact D, which is connected to the frame of the instrument. The currents through the tens line start from the battery M, pass through P and the electromagnet marked "Tens" to C, thence to B through the tens line to the subscriber's instrument, and back to the battery through the common return. The armature of the tens electromagnet acts on the rack F and lifts the shaft A bodily by a number of teeth on F corresponding to the number of current impulses sent (that is to the number of tens in the figure required). The third series of impulses, through the units magnet, turns N through a number of teeth corresponding to the number of units. The shaft A carries a "wiper," W, of copper strip, this moving over a number of rows of contacts arranged in an insulating segment Z of impregnated plaster of paris. There are 10 rows, and 10 columns of these contacts, one for every subscriber to the exchange. The first current-impulse on the unit line brings the wiper in position one tooth behind the first contact, the impulses along the tens line cause it to find the row corresponding to the tens required, and the next series of currents along the unit line rotate the wiper until it reaches the contact required. This leaves the tens and units wire of the calling subscriber connected to the subscriber wanted, and the former rings up. After the conversation is concluded, the action of hanging the receiver on the switch hook sends two successive currents to line, the first through the units, and the second through the tens line, and things are restored to their normal condition.

It has been found necessary to devise means for preventing subscribers cutting in on lines in use. Every subscriber's line is connected to the switches of the other subscribers through an insulated pin, marked "normal pin" in the cut, connection only being made to this when the shaft A is in its normal position. This effectually prevents the line of the subscriber who has called originally from being reached by any other subscriber until the former has finished his conversation. But to protect the called subscriber during the conversation is not such a simple matter. It is necessary to multiple all the subscribers again at each switch on a segment Y, in an exactly similar manner as on Z, but in this case connection is made by an insulated wiper, V. A system of switch contacts is arranged in connection with the wipers V and the electromagnet H, so that if a second connection is made, at another switch, to a line already connected, the electromagnet H of the second calling subscriber is energized and actuates a spring switch which opens his own circuit.

The current used to actuate the electromagnets in a 100-subscriber exchange is about half an ampere. The contact disk of the subscriber's instrument sends nine current-impulses per second. The resistance of the units coil is 16 ohms, and this coil is in circuit during speaking. In the case of larger exchanges this cannot be permitted, a coil of higher resistance and self-induction must be used. A bridging retardation coil, with a connection to the middle point, is then employed.

In exchanges fitted for over 100 subscribers, in addition to switches similar to those already described, there is added for each subscriber what may be called a junction-wire switch. Taking a 1,000-subscriber exchange, for instance, the subscribers are arranged in groups of 10. Each subscriber has his own junction switch, and there are also 10 of the previous type of switches for every group of 10 subscribers, the latter switches being placed below the junction switches. The first of the three sets of current-impulses, sent by a calling subscriber, actuates the junction switch, and connects his line to the one of the 10 junction lines corresponding to hundreds. Each of these lines is connected to one of the lower row of switches, and the currents corresponding to the tens and units demanded actuate this second switch, and so connect the subscriber through to the one he desires connection with. The arrangements to prevent connection to an engaged line or engaged junction line are similar to, but necessarily somewhat more complicated than those used in the smaller exchanges.

It will be noticed that several important modifications have been made since this system was introduced into this country. The English telephone men, it appears, are not satisfied with the record of the system thus far. The London Electrician, for instance, discusses the question of comparative first cost and says: "The makers claim that the actual cost of a board for 5,000 subscribers is less than that of a manual board of equal capacity. If this claim is substantiated in practice, if the repairs and maintenance account is below the amount now paid to the operators in wages, if the apparatus can be maintained in repair without interruption to the continuity of connections, and if the net gain in cost is sufficient to cover the increased price of the subscribers' instruments, then the manual board has



AUTOMATIC TELEPHONY IN ENGLAND—DIAGRAM OF CONNECTIONS.

a very formidable rival. But although the automatic telephone exchange is a marvel of ingenuity and reflects great credit on those who have invented it and worked out its elaborate and complicated details, several years of trial must elapse before its superiority can be considered proved, and at any rate at the present moment the apparatus of existing telephone exchanges need not be considered obsolete, neither is it necessary yet for the telephone operator to seek fresh fields for her talents."

English and American Telephone Practice.

[From the London Electrician.]

It is interesting to note the disparities in American telephone practice, and these disparities are well brought out by the descriptions, in another part of this issue, of three American exchanges. As a fourth, a new 4,000-subscriber exchange just completed by the Bell company in St. Louis, might have been described. The last combines nearly all the most modern improvements in exchange equipment. The underground system in St. Louis has already been described, and to this is added a system of automatic calling and ringing off by the action of the subscriber removing and replacing his receiver on the switch hook, a method somewhat similar to that originally introduced by the British postoffice. The latest improvements in common working have been adopted, including the successful training of the subscriber to understand the meaning of a "busy back" note, a signal far more and no less irritating than the verbal reply of "engaged," but saving one action in operating. Finally, the chief operator's board is provided with indicating lamps, one connected to the indicator at each operator's position, so that a check is had on the promptness of replying to calling and clearing signals. The last improvement is also in use in some continental exchanges, and it might with advantage be introduced into this country.

The new John street exchange in New York offers a strange contrast to this. A clumsy system of transfer working is employed instead of multiple switching, although the exchange is equipped for no fewer than 1,200 subscribers. What may be the reason for this is difficult to see, unless it is a disinclination to pay royalty for the use of multiple working, this being, we believe, still protected by patents in America. That nearly every local connection in a 1,200-subscriber exchange should have to be dealt with by two operators is distinctly a retrograde step. The small exchange in La Crosse also uses a novel system of transfer working, but in a small exchange, where the question of a cheap rental is the foremost one, this is more excusable. In commenting on American methods it may also be mentioned that the breastplate transmitter appears to be very little used in that country, in spite of its obvious convenience. It can adjusted closer to the operator's mouth than the suspended transmitter—which is even employed in the new St. Louis exchange—and it materially lessens the noise in the switch room. We also notice that the number of operators employed appears to be relatively less than in this country. In La Crosse one operator attends to the demands of 100 subscribers; in the John street exchange there are 16 operators' positions for 1,200 subscribers, and in St. Louis the three operators of each section attend to 260 subscribers. In the "Avenue" and "Bank" exchanges in London the number of subscribers per operator's position is 50, the mean for all the metropolitan exchanges being 52.5; in Leeds and Liverpool one operator attends to 66 subscribers during the busier hours of the day, and in Manchester, where the call-wire system is used, the figure is again 50. Are the American operators smarter than the English ones, or is it that the subscribers are more patient?

Right to Use Streets for Telephone Purposes.

One of the most important legal questions confronting those who wish to establish or extend telephone systems is whether the erection of poles and stringing wires thereon, in a street, is within the contemplated use of the street, or is an additional burden upon the title of the abutting proprietor, who owns to the center of the street, subject to the rights of the public to use the street for recognized street purposes, requiring compensation to or consent from him.

This was the principal question in the case of Magee against Overshiner, which was a suit brought to compel, by a mandatory injunction, the removal of a telephone pole placed in the curb-line of the sidewalk in front of Magee's property, fronting upon one of the principal streets of the city of Logansport, Ind. The pole had been placed and the wires strung during the night, after a protest. From a judgment in favor of the owner of the telephone system, who was made the defendant, an appeal was taken to the Supreme Court of Indiana, which affirmed that judgment, March 29, 1898.

In the accompanying opinion the Supreme Court says that the decisions of the courts of this country, so far from establishing a definite rule upon the question involved, are at such variance as to render hopeless any effort to reconcile them. And text writers justly renowned, it adds, have grouped many of the cases, which it cites, and have variously expressed the opinion that the weight of authority forbids the use of an urban way for telephone equipment. But the court declares that it has found no analysis of the cases, and no attempt by such writers to classify the cases applying to urban and suburban ways, and no effort made by them to consider the reasons supporting the cases which uphold the use as within the scope of proper street uses.

Because a street was dedicated or condemned before electric inventions for lighting, communicating oral and telegraphic messages, and propelling street cars were thought of, the Supreme Court does not believe that it will suffice to say that it could not therefore have been condemned or dedicated in contemplation of the uses therein of such inventions. It must be, however, that the contemplated uses should be deemed to have been, not only in the walking, riding upon horseback and in wagons or other vehicles drawn by animals, in the going and returning upon business, social, religious or political missions, but also by such methods of travel and communication, in addition or in substitution for those that might come into vogue and be accepted and recognized as proper and important uses of the street in the varying needs and demands of commerce, and the relations of man to man socially and otherwise. That a dedication or condemnation is deemed to comprehend uses not actually in the minds of the parties at the time is seen from the almost unvarying rule that the electric street-railway systems are not a new use and an additional servitude, but are a new method of enjoying an old and ever existing use.

Furthermore the Supreme Court declares that it observes no means of distinguishing against the telephone equipment, on the ground that its poles are not in motion as are ordinary instruments of travel, since the permanent occupancy by the trolley poles, the gas and water pipes, etc., is maintained. On the

other hand, it pronounces the telephone more clearly a substitute for the old methods of the communication of messages between persons within the city than the telegraph, laying some emphasis on the fact that the former can be used for that purpose directly, and by persons without special skill.

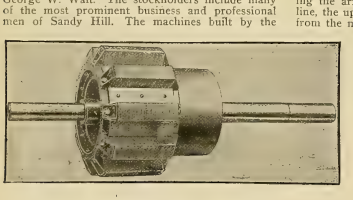
Consequently, the Supreme Court of Indiana concludes that the reasonable use of the streets of a city for the equipment of a telephone system is not a new and additional servitude, for which the abutting property owner is entitled to compensation. Nor does it agree that the ordinary pole and wires are a special injury to the enjoyment of the abutting property.

Last of all, the Supreme Court holds that it is no reason why a telephone system may not be owned and conducted by an individual, merely because the Legislature has granted such rights to corporations, inasmuch as an individual may conduct any proper business without legislative assent, unless there has been some legislative restrictions upon such right.

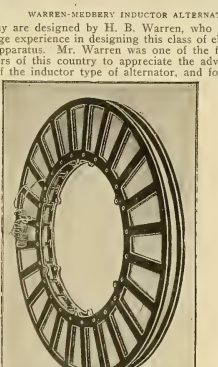
Warren-Medbery Inductor Alternator.

A late and interesting alternator of the inductor type is that built by the Warren-Medbery company of Sandy Hill, N. Y., details of which, from a 150-kilowatt machine recently installed in the station of the Ballson Electric Light company of Ballston Spa, N. Y., are illustrated herewith.

The officers of the Warren-Medbery company are: President and general manager, H. J. Medbery; vice-president and electrical engineer, H. B. Warren; secretary, H. E. Edmarsh; treasurer, George W. Wait. The stockholders include many of the most prominent business and professional men of Sandy Hill. The machines built by the company are designed by H. B. Warren, who has had large experience in designing this class of electrical apparatus. Mr. Warren was one of the first engineers of this country to appreciate the advantages of the inductor type of alternator, and for a number of years he has devoted particular attention to this branch of engineering. The result is a machine combining, in the highest degree, all the desirable features of modern alternators.



WARREN-MEDBERY INDUCTOR ALTERNATOR.



WARREN MEDBERY INDUCTOR ALTERNATOR.

The inductor alternator is deservedly a popular and satisfactory type of machine from the operator's point of view, as is shown by the fact that in so many of the increases and additions to existing central-station plants inductor machines are specified. This is very significant, as it demonstrates that experienced operators of electrical apparatus have become convinced that the remedy for many of the trials of the station manager lies in the use of this type of generator.

Another important consideration for any class of work is the insulation of the armature coils. This can be best obtained in stationary armatures, because in such there is practically unlimited space available for insulation, and the coils are not subjected to the mechanical strains accompanying revolving armatures. In inductor armatures the coils are carried on a rigid structure, and may be insulated to any required degree; 10,000 volts is a practical working pressure. The economic value of this feature of power transmission is that the generator, operating at the pressure required on the transmission lines, calls for no investment in step-up transformers and cuts out the constant loss of power which occurs in such devices.

The accompanying illustrations of parts of the standard single-phase belt-driven generator show clearly the characteristics of these machines. The lower half of the frame, with the base and supports for bearings, constitutes a single casting, insuring great strength and rigidity in the machine, guaranteeing the accurate centering of the revolving inductor while assembling the machine and maintaining perfect alignment while in operation. The bearing sleeves are lined with a high grade of anti-friction metal; the bearing surfaces are unusually large and the peripheral speed of the shaft in the bearings is moderate. The bearings are self-oiling from an oil reservoir of large capacity, and the distribution of oil throughout the bearings is remarkably abundant, being effected by a peculiar arrangement of oil ducts in the interior of the bearing sleeves. The bearing sleeves are made solid, as being the most convenient form for babbitting, in case it should become necessary to re-line the bearings. The supports for the bearings are so designed that when it is desired to remove a bearing sleeve the only operation necessary is the removal of the bearing cap, after which the sleeve may be slipped endwise off the shaft. The sub-base carries polished steel skids and the machine rests upon these skids with an interposed layer of babbitt, accurately shaped to the configurations of the skids. By means of a powerful ratchet and adjusting screw the belt tension may be easily and quickly regulated.

By the removal of the two frame bolts and opening the armature circuit on the horizontal central line, the upper half of the frame may be lifted away from the machine. The upper half of the machine carries the upper half of the armature and the corresponding armature coils. The revolving inductor is surrounded at its smaller end by the field coil, which is attached to an annular yoke casting. After the upper half of frame and armature are removed, the revolving inductor, field coil and yoke may be lifted out. By this method of construction all of the coils of the machine are readily accessible for inspection and repairs.

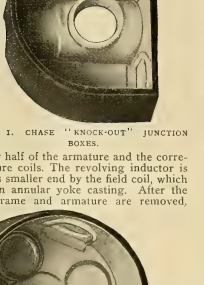


FIG. 1. CHASE "KNOCK-OUT" JUNCTION BOXES.

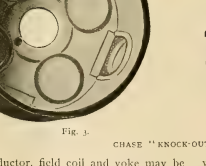

Fig. 3.

CHASE "KNOCK-OUT" JUNCTION BOXES.

The armature body is built up of a special grade of soft steel, and the method of handling the metal prevents any injury to its structure which would increase the losses due to magnetization. For the armature metal of a very thin gauge is used, and the sheets are served on both sides with an insulating compound which is not affected by heat or age. By this means, the armature eddy currents are thoroughly broken up, and no loss of power occurs from heating. In addition to this, there is a series of recesses between the cast frame and the outer circumference of the armature. These recesses are entirely internal, and the exterior of the frame casting is retained smooth and symmetrical without unsightly openings for ventilation purposes. The machines operate remarkably cool, as no point rises over 50 degrees Fahrenheit, even when operated continuously under 10 per cent. overload.

The armature coils are machine wound and of a plain oblong type, with easy corner bends. This simple form of coil reduces to a minimum the hazards of winding, for neither the structure of the wire nor its covering are subjected to the strains attendant upon the winding of complicated shapes with sharp bends, or of coils which are forced into place in the armature. These coils are thoroughly saturated with an insulating compound which has no affinity for the copper, but preserves the covering of the wire. For retaining the shape of the coil a single layer of untreated tape is wrapped all around, and over this a thick coat of waterproofing compound is applied, which makes it practically impossible for moisture or oil to penetrate the insulation of the coil. Through all the processes of handling and treatment of coils, great care is exercised to prevent injury to the wire and its covering, and no compounds are applied which will deteriorate with age, or in any way attack the wire or covering. This is accomplished, too, without swaddling the coils in a thick or bulky envelope, which would interfere with a ready radiation of heat from the interior of the coil. The insulation of coils is mainly obtained from a special insulating trough, which forms the interior lining of the coil slots in the armature. These troughs are semi-flexible, practically non-combustible, will not absorb moisture, are not affected by oil, and will not deteriorate with age. The troughs for 1,000 volts and the troughs for 2,000-volt armatures are subjected to a breakdown test of 6,000 volts, and the troughs for high-voltage armatures are subjected to a minimum of 15,000 volts breakdown test.

After the troughs and coils are in place in the armature, an insulating perforated cover closes up the coil slot and secures the coils and troughs in position. The slot cover is perforated, which allows the revolving inductor to drive a continuous current of air around the coils. This produces such a cooling effect that these machines may be operated continuously, under heavy overloads, without serious heating of coils.

The field coil of the machine is of quite novel construction, for in effect, it is simply a coil of wire suspended in air; that is, it has the insulation, the radiating surface and the free circulation of air around it, as if it were merely a coil of wire suspended in space, in contact only with a number of insulating supports. The field-coil case consists of two ring castings, spaced apart with rods of insulating material, and the sides lined at numerous places with narrow strips of narrow material. There is no floor in the case, and the sides are cut away, except where backing is required for the insulating strips. The wire is wound over the insulating rods and is in contact only with the rods and strips; it is a skeleton case, which leaves exposed the outer and inner circumferences of the coil, and practically both sides. The rotation of the inductor produces an agitation of air all round the field coil with a constant circulation outward through the openings in the yoke, and the coil will stand severe overloads without injury.

The machines are handsome in design, of fine finish and incorporate the highest grade of workmanship. The efficiency is remarkably high, being equal in this respect to the best designs of direct-current generators, and the inherent regulation is said to be by far the best yet obtained in alternators of any type. The placing of all the armature coils in a single wreath at one end of the machine, and the surrounding of every armature pole with an armature coil, is thought to produce a better combined efficiency and regulation and a more correct form of current wave than any other construction. To these features the Warren-Medbery company has united a robust and workmanlike construction, comprehending simplicity, accuracy and durability, forming a conjunction of desirable features and producing a practical and reliable machine.

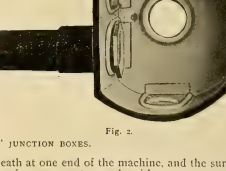

Fig. 2.

Chase "Knock-out" Junction Boxes.

L. A. Chase & Co. of Boston ask attention for their new "knock-out" outlet and junction boxes for inside wiring. This box is made of special grade of iron and heavily coated with a hard, black enamel, having the best insulating qualities. It is so constructed as to have, at frequent intervals on its surface, thin webs or films which a slight blow of a hammer will "knock out," leaving round holes for outlets in as many combinations as are generally required.

The method of attaching the box to the conduit is new and has many advantages. A hollow bushing or nipple, which is threaded on the exterior and smooth and insulated with enamel on the interior, is passed through the hole made in the box at the point desired, and screwed into the coupling on the end of the conduit. This makes a perfect

mechanical connection, which can be made watertight. By means of this nipple wires can be readily pulled through the tube into the box without any danger of abrasion or injury to the insulation of the wires. The Chase box can be instantly disconnected from the conduit by unscrewing the nipples from the inside of the box, thus allowing the box to be withdrawn, regardless of the number of conduits that enter it.

Fig. 1 represents the ceiling outlet box, which may be used for the outlets where the conduits enter from the side or the back of the box. The hole in the center of the box allows for a support for the fixture, or, if used in combination work, the gas-pipe nipple to come through. However, in com-

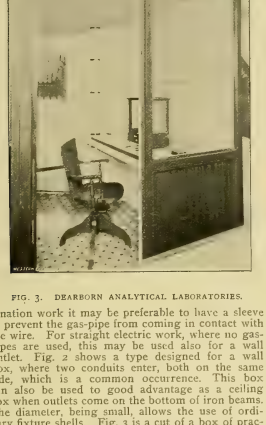

FIG. 3. DEARBORN ANALYTICAL LABORATORIES.

bination work it may be preferable to have a sleeve to prevent the gas-pipe from coming in contact with the wire. For straight electric work, where no gas-pipes are used, this may be used also for a wall outlet. Fig. 2 shows a type designed for a wall box, where two conduits enter, both on the same side, which is a common occurrence. This box can also be used to good advantage as a ceiling box when outlets come on the bottom of iron beams. The diameter, being small, allows the use of ordinary fixture shells. Fig. 3 is a cut of a box of practically the same style as No. 2, with the exception that it has a recess in the bottom, so that it will straddle the tee of the gas-pipe at the outlet. This is a desirable feature in places where the plaster comes close.

Dearborn Analytical Laboratories.

The four small pictures presented herewith show views of the offices and laboratories of the Dearborn Drug and Chemical Works of Chicago. Fig. 1 gives a view of the main laboratory; Fig. 2 shows the private laboratory; Fig. 3 represents a corner of the balance room and Fig. 4 is a picture of the general office.

Since the inception of this institution, some nine

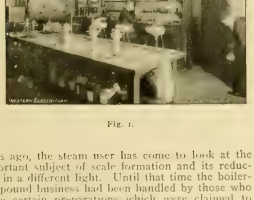

FIG. 1.

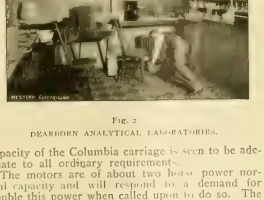

FIG. 2
DEARBORN ANALYTICAL LABORATORIES.

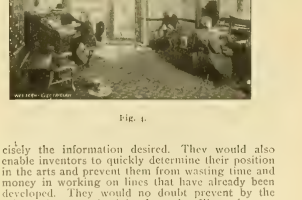

FIG. 4.

years ago, the steam user has come to look at the important subject of scale formation and its reduction in a different light. Until that time the boiler-compound business had been handled by those who made certain preparations which were claimed to meet all the different troubles caused from the thousands of feed-waters throughout the country. The Dearborn people have had a hard fight to convince a skeptical and unbelieving public that this question could be practically and economically solved; but this institution, with W. H. Edgar at its head, realizing the vast expense that scale formation and other troubles from feed-waters was to the steam user, has scientifically and honestly built up what is to-day one of Chicago's most successful and healthy enterprises. All analytical work, such as analyses of waters, scale, oils, etc., and a report and consultation on the analyses, are given freely to the steam user, and, from the busy appearance of the company's well-equipped laboratories, it may be judged that it is becoming thoroughly appreciated by the great power-producing public.

Columbia Electric Carriage.

Horseless carriages are gradually enlisting the favorable consideration of Americans. We are as yet far behind Europeans in the adoption of vehicles of the kind for the practical purposes of business or pleasure, although it is conceded that in point of manufacture we are well ahead of makers on the other side. An automobile club has been formed at Buffalo, which has miles of asphalted streets and fine suburban driveways splendidly adapted to this form of pleasure riding, and a similar club is soon to be organized at Newport, where, last season, a number of Columbia motor carriages, built by the Pope Manufacturing company of Hartford, were in daily use and served to thoroughly stir the summer colonists to an appreciation of the enjoyment of riding in these splendidly appointed, silent and smoothly running vehicles. The Columbia carriage is already engaging the attention of many of the wealthy residents of other cities, in several of which automobiles in actual use are no longer a strange sight. The exhibit of the Pope Manufacturing company at the electrical exposition, now in progress at the Madison Square Garden, New York, is one of the most prominent and interesting features of the entire exhibition, and one which creates a great deal of favorable comment from both the technical and lay points of view.

As may be noted from the accompanying cut, the Columbia carriage resembles a Stanhope phaeton in general appearance, and the general furnishings and upholstering are of the most expensive and durable character. The Pope people began experimenting in the line of developing a satisfactory automobile about three years ago, and shortly afterward alloted a fully equipped factory to the new industry and formally organized a motor-carriage department. The company is convinced that the Columbia electric carriage, with its almost noiseless action and perfect ease of control, comes very near to being the ideal automobile. It is the embodiment of several years of development of the best mechanical and electrical equipment that could be devised.

The motive power is derived from storage batteries which combine great efficiency with the least weight consistent with reasonable life. The batteries can be charged from any direct 110-volt current circuit, such as are commonly used for lighting. Little attention to the charging process is required after the batteries are connected with the circuit, as the current is automatically cut out when the process is complete. A meter at all times shows to what extent the batteries are exhausted, so there is no danger of running out of power away from a source of supply. The cost of charging should not exceed 50 cents if the current is taken from an ordinary city circuit. The batteries are adequate to drive the carriage about 30 miles on good, level roads without recharging. With a view to ascertaining the mileage requirements of persons who "drive all the time"—doctors, expressmen and other constant users of vehicles—the company entered into a searching investigation of the subject. About 18 miles a day was found to be the average mileage of these continuous drivers. So that the mileage capacity of the Columbia carriage is seen to be adequate to all ordinary requirements.

The motors are of about two horse power normal capacity and will respond to a demand for double this power when called upon to do so. The carriages are designed for a maximum speed of upwards of 12 miles an hour on good roads, although speeds are provided for of six and three miles per hour. The same speeds can be obtained backward through a simple reversing process. The steering apparatus is extremely simple, and is manipulated with the greatest ease.

The carriage may be "hitched" when left standing in the street or elsewhere by removing the emergency plug, which is not too large to readily slip into a vest pocket. Until the plug is replaced the carriage cannot be again moved by its own power. A powerful foot brake, operated by very light muscular effort, will "hold" the carriage on any grade, or quickly bring it to a standstill whenever desirable.

Special material, manufactured and tested for this particular purpose, is used in the frame, body, top, upholstering, etc. The wheels are designed to overcome all objections to other existing types, as noted by the company's experts after a long period of careful observation and study. They are Hartford single-tube tires, especially constructed with the object of securing the greatest possible durability, and which are practicably non-puncturable. The performance of these tires has been entirely satisfactory. All parts of the running gear that might be injured by exposure to mud or dust are securely enclosed. Each detail of construction has been worked out to provide the greatest strength with the smallest possible sacrifice of lightness and elegance.

Patents and Inventions.

[Special correspondence of the Western Electrician.]

Washington, May 16.—The commissioner of patents has taken up the subject of securing a concise

COLUMBIA ELECTRIC CARRIAGE.

record of the work of the Patent Office, and, with this in view, has recommended an appropriation for the purpose of completing the "abridgment" commenced several years ago.

The British Patent Office publishes in book form abridgments of patents relating to the several classes of invention. These are of very great value, not only to examiners in the United States Patent Office and to inventors, but to the general public. They afford a ready means of gaining full and accurate information concerning patents granted in England in all classes of invention, and enable manufacturers and artisans to readily determine what inventions have become public property through expiration of patents covering them and what are protected by patents still in force and therefore not to be manufactured or used, except with the consent of the owners of the patents, without risk of suit for infringement.

Nearly every United States commissioner of patents for the last 40 years has recognized the necessity for the publication of like abridgments of United States patents. It has been repeatedly pointed out that such abridgments would be of the greatest value to inventors and to the public. Hundreds of thousands of inventions, many of them of great value, have, by expiration of the patents granted on them, become free to the public to make and use; but those who might engage in the manufacture of such inventions are often unaware of their rights in relation to them. Such abridgments would furnish in compact and convenient form precisely the information desired. They would also enable inventors to quickly determine their position in the arts and prevent them from wasting time and money in working on lines that have already been developed. They would no doubt prevent by the information contained in them the filing of many useless applications and would ensure the filing of applications generally in better shape than at present. The work of making these abridgments was begun in 1881, but was discontinued for lack of the necessary appropriations and has never since been taken up. Abridgments could have been made covering patents granted prior to that year, at that time, at comparatively small expense, and they could have been brought up to date each year since

then for a small annual appropriation. With the great mass of material which has now accumulated the expense would be considerable, but could be met, as can all other needs of the office, without exceeding the annual receipts. A full set of such abridgments would be practically indispensable to attorneys practicing before the Patent Office. There are more than eighteen hundred of these upon the register. Abridgments relating to particular arts would undoubtedly be largely called for by inventors and manufacturers throughout the country.

A full report of the conference of the Union for the Protection of Industrial Property, which was held at Brussels last December, has been prepared by the Hon. Bellamy Storer, minister to Belgium, and Francis Forbes, the United States delegates to the conference. The conference was attended not only by delegates from 15 of the states of the union, but by representatives from seven states which have not yet entered the union, among them Germany and Japan.

The propositions for amendment of the convention, submitted by the United States, looking toward reciprocity in the matter of fees and the requirement of working, and the matter of inventions belonging to certain classes which are patentable in the United States but not in certain other countries, were held by the conference to be contrary to the general spirit of the convention, but several solutions of the difficulties complained of were suggested which would not be obnoxious to the convention, such as requiring of any inventor who has applied for a patent in a foreign country before applying in the United States, first, the payment of the same fees in the United States which are required in the foreign country in which application is made; second, the limitation of the patent granted in the United States to the invention protected by the foreign patent, and, third, providing that the patent be granted in the United States within the time within which working is required in the foreign country.

As the fees exacted in many foreign countries and the annual taxes on patents and the requirements of working the invention in each country in which it is patented are extremely onerous upon American inventors and manufacturers, it is believed to be but right that foreign inventors should not be permitted to obtain patents in the United States under easier conditions than they can in their own countries.

The proposition submitted by the United States for the purpose of removing any question as to the effect upon the right of priority of the amendment of an application found necessary in the progress of the examination into the novelty of the invention was favorably received, but was not incorporated in the convention, for the reason that it was believed unnecessary, it being the opinion of the conference that it was "incontestible that the restrictions given to the original description, during the preliminary examination, cannot prejudice the right of priority established by article 4." It had been generally understood that a United States inventor seeking to secure the benefits of the "delay of priority" of seven months under the convention must file in the foreign countries the application as originally filed here, instead of the application in the amended form in which it became a patent. Under the present understanding of the convention, the United States inventor, having complied with the requirements here, may at once offer his invention for sale in a foreign country, or otherwise bring it to the notice of manufacturers there, and yet on making application at any time within seven months from the date of his application here, obtain there a valid patent.

A proposition to so amend the convention that patents granted in the several countries shall be mutually independent, that is, that a patent granted for 14 years in one country shall not shorten the term of a patent subsequently in a country in which the normal term is 17 or 20 years, received the support of the United States delegates and was adopted by the conference.

The proposed extension of the "delay of priority" to one year, the proposition that patents worked to the extent required in the country of origin should not be forfeited for non-working in other countries for at least three years from the grant of the patent, and certain propositions relating to trademarks, were discussed very fully, but had to be left to be settled by correspondence. All of these propositions, excepting the particular proposition restricting the registration of trademarks, were favored by the United States delegates.

Among the papers submitted with the report is a statement of the inventions excluded from protection in a number of foreign countries and a statement of the requirements as to working the invention made in certain countries. In some countries the failure to manufacture the invention in the country within one year invalidates a patent granted on the invention. In others, two years, or even three years, are allowed and importation of goods made under the patent is prohibited. This means that the manufacturer of an American invention must establish factories in each of these countries or give up patent protection in them.

Representative Hicks, chairman of the House committee on patents has introduced a bill authorizing the president to appoint three commissioners, whose duty it shall be to revise and amend the laws of the United States concerning patents, trade and other marks, and trade or commercial names, which shall be in force at the time such commission shall make its final report, so far as the same relates to matters contained in or affected by the Convention for the Protection of Industrial Property concluded at Paris on March 20, 1883, the agreements under the convention concluded at Madrid in April, 1891, and the protocols adopted by the conference held under such convention at Brussels last year, and the treaties of the United States, and the laws of other nations relating to patents, trade and other marks, and trade or commercial names. The commission is to report to Congress at once, and the report shall be made to indicate any proposed change in the substance of existing law, and shall be accompanied by notes which shall briefly and clearly explain the reasons for proposed changes. The report shall also be accompanied by references to treaties and foreign laws relating to patents, trade and other marks, and trade or commercial names, which, in the opinion of the commissioners, may affect citizens of the United States.

Telegraph Tournament in New York.

Telegraph operators from all over the country contested for prizes at the electrical exposition in Madison Square Garden, New York, on Saturday. During the afternoon three classes tested their ability at sending and receiving messages from one of the anterooms of the concert hall in the building into the main auditorium. In all about 25 young women and men participated under the supervision of Frederick Catlin, a well-known expert operator. In the women's class, which required the sending of the greatest number of words within the period of five minutes, the first prize being $80 and the second $60, the winners were Miss J. McManus, employed by the Postal Telegraph company in New York, first; Miss Emma R. Vanselow, New York, second. In the class requiring the sending of 230 words within five minutes, the first prize was $90, and was won by Charles F. Edney of the Associated Press. F. M. McClintock of the Associated Press, Memphis, Tenn., won the second prize, $70. In the 240-words class J. D. Hinnant, employed by the Anglo-American Telegraph company, won the first prize, sending 252 words, and F. M. McClintock of Memphis, Tenn., won the second prize, sending 243 words. David C. Grant of the Toledo Commercial, Toledo, O., was highly commended in both the 230 and the 240-word classes.

There were only three entries in the code-sending class. These were G. W. Conkling, New York, who won by sending 345 words in five minutes; W. M. Gibson, New York, 330 words, and C. F. Edney, New York, 279 words. The title of champion sender was won by W. M. Gibson, who, without code abbreviations, sent 254 words in five minutes. Frank L. Catlin of Albany was second with 253½ words. Gibson broke the previous record of 248 words, made in 1893 by F. J. Kihm of Brooklyn.

The judges selected for the tournament were A. S. Brown, F. E. Jones, Charles Shirley, F. F. Austin, P. J. Tierney, E. W. H. Cogley, J. H. Bunnell, P. B. Delany, T. J. Smith, T. C. Martin, W. D. Weaver, J. B. Taltavall, G. H. Guy and Colonel A. B. Chandler. Additional interest was given to the occasion by the presence of Thomas A. Edison, who, as is well known, was a skillful telegrapher at one time of his life. He was prevailed upon to assist in the judging, although, as he laughingly confessed, he was of little practical use in that position, as the deafness from which he suffers prevented him from distinctly hearing the ticking of the receiving instrument.

American Institute of Electrical Engineers.

In compliance with the constitutional provision, the fifteenth annual business meeting of the American Institute of Electrical Engineers was held at 12 West Thirty-first street, New York, on Tuesday, May 17th, at 8 p. m. The annual report of council was presented, including the financial statements of the treasurer and secretary.

The annual election of officers was, of course, the principal event, and, as usual, it resulted in the election of the council ticket, which contained the following names:

President, Arthur E. Kennelly.

Vice-presidents, Robert B. Owens, William Stanley, Cary T. Hutchinson.

Managers, Herbert Lloyd, Samuel Sheldon, George F. Sever, Charles P. Steinmetz.

Secretary, Ralph W. Pope.

Treasurer, George A. Hamilton.

When the business had been transacted the members visited the electrical exposition at Madison Square Garden.

It was announced that applications had been received from the following candidates for associate membership, which will be acted upon by the council at its meeting June 22d:

Walter C. Allen, Washington, D. C.; Frank Henry Dexter, Ithaca, N. Y.; P. M. Downing, Blue Lakes City, Cal.; Joseph Lyons, Washington, D. C.; George A. Damon, Chicago, Ill.

Members who desire to present papers for the general meeting at Omaha, June 27-29, are requested to communicate with Herbert Laws Webb, 15 Dey street, chairman of the committee on papers and meetings, or with the secretary.

Surgery with a Magnet.

[From the Cleveland Leader.]

A physician of Canal Dover has just performed an extraordinary surgical operation by means of electricity. The patient is little Erma Wallick, the five-year-old daughter of Felix Wallick. The child in romping on the floor accidentally ran an ordinary sewing needle into her leg at the right knee-joint. In attempting to pull it out the father broke off the bit of steel, leaving more than half of it imbedded in the flesh, and when she was taken to the doctor repeated probing failed to locate the fragment of needle. At the latter's suggestion the child was taken to the power house of the Tuscarawas Electric company and placed on the dynamo in such a manner that the right knee-joint pressed against a powerful magnet of 125 horse power. The little tot was kept almost continuously in this position for eight hours. The treatment was heroic, but the joint had become so painful and swollen that the magnet treatment was resorted to in the extremity of saving the limb. This powerful force failed to draw the needle to the surface, and a smaller magnet connected with the dynamo and having its full force was made in such a form that it could be inserted in an incision at the joint. The baby was chloroformed, the leg laid open with the knife, and the magnet introduced. When it was withdrawn the troublesome bit of steel clung to it, and the experiment was a success.

The Pacific Cable Question.

[From the London Times of April 11th.]

The development of events in the Far East and the addition of Wei-hai-wei to the list of British posts on the Pacific lend special interest to the renewal of activity with regard to the construction of swifter means of communication between the scattered British communities. The Australian premiers in conference have agreed that if Great Britain and Canada will contribute two-thirds of the cost of a Pacific cable, Australasia should contribute one-third. In Canada an influential deputation has waited on the premier and laid before him a proposal that a Pacific cable trust should be created under authority of the parliaments interested in the scheme, with power to raise the necessary funds and proceed to the construction of the cable. In this country it is understood that as soon as the Australasian and Canadian colonies shall agree in manifesting a strong desire for the construction of the line, any proposal which they may make to that effect will receive at least favorable consideration.

The need for a Pacific cable is becoming every day more potent, and the rule which applies to all other commercial enterprises will no doubt hold good, that, when the advantages of a new opening have become fully apparent, if one man holds back another will certainly come forward to profit by the offered chance. That a Pacific cable will be made before long is hardly open to doubt. The question with which the imperial and colonial governments are playing is whether that Pacific cable shall be in British or in foreign hands. The position, very briefly summarized, is as follows: Commercial civilization has been spreading eastward and westward from its more active centers, till at both extremities its extension has reached the shores of the Pacific. It finds the largest ocean of the inhabited world as yet untraversed by a single line of telegraphic communication. When the West wishes to communicate with the East or the East with the West across the dividing water, the message has to be sent backwards round two hemispheres. Yet swift communication is the soul of commerce, and commerce is the soul of every flourishing modern community established on the shores of the Pacific. The British communities of Canada, Australia and New Zealand, the western states of America, the scattered island populations, now first coming to importance, are in their nature industrial before anything. The name of the East Indies is almost synonymous with trade. Japan has passed through an industrial second birth. Russia is pushing industrial enterprise on the northern Asiatic coast. France has not shrunk from heavy cost to establish a commercial footing on the south. Germany has made her latest move in the interests, we are asked to believe, of the protection of her commerce. Thus, north and south and east and west, the ocean is surrounded by rival nationalities. In presence of these waiting powers indications are given that the immense commercial field of China is about to be thrown open. Instantly the waters of the Pacific are alive. The military and political movements which have taken place are but the forerunners of other intercourse. To suppose that the competing communities will remain indefinitely without the means of telegraphic communication so essential to the success of individual aims is to ignore all the teachings of experience. Under the protection of one power or another, a cable connecting the lines of the eastern with the western and of the southern with the northern continents will certainly be made. All that is doubtful is whether that power will be British. We have declared our policy in those seas to be commercial. Here is a step of evident commercial advantage to

be taken, and as the matter at present stands the most decided utterance which appears to have been made upon the subject is to be found in a communication received by the Hawaiian government in the first week of February, to the effect that the French cable connecting Australia, via New Caledonia, Tahiti and the Sandwich Islands, with San Francisco will immediately be laid. If this information is correct, such a Pacific cable would, of course, be under the immediate control of France and the United States.

The cost of an all-British cable connecting Canada with Australasia would be about £1,500,000. The construction has been tendered for by competent contractors at that figure. It has been estimated that a diversion of less than half the existing telegraphic business of Australasia with the northern hemisphere to its line would render it fully self-supporting, and as the telegraphic business of Australasia, which is rapidly increasing, would of necessity be stimulated by increased facilities for communication with growing markets, the presumption is that a great deal more than the required quantity would in the course of a few years pass over the Pacific cable. The trunk line of cable once established, branch lines can easily be constructed to connect it with important points. One terminus under British protection in Australasia and another in Canada, one branch, if necessary, to join the San Francisco connection with Hawaii and another to Japan and the China ports, would create a British network of cable communication which would for a long time to come meet the principal commercial needs of the Pacific. Interest at three per cent. on the whole initial cost of the Canadian and Australian line would be covered by £50,000 a year. To guarantee working expenses and the necessary loan would in no circumstances entail more than a trifling expense upon the guaranteeing governments, and if the apparently reasonable anticipation of commercial success prove to be well founded there will be substantial profit. The benefit to British commercial interests cannot be a question of doubt. The most practical proposal which has been formulated for consideration is that the five governments of Canada, New Zealand, New South Wales, Victoria and Queensland, or any four of them, shall enter into a joint arrangement for establishing an electric cable across the Pacific, sharing equally in costs and profits, and that the imperial government shall be invited to guarantee or lend one-third of the capital, or assist in such manner as the home authorities may determine. The original suggestion in connection with this scheme was that, if it were accepted, the official representatives of the colonies in London should be charged with the duty of ascertaining how best to carry out the proposal. The present proposal would appear to be that, in the event of the acceptance of this or some alternative scheme, a trust should be formed for the purpose of carrying it into effect.

It has been the fashion to treat the Pacific-cable scheme as one of impressive magnitude. As a matter of fact, it is a scheme of wide utility, but of financial dimensions so modest that one rich man could proceed to the construction of the cable out of the resources of a private fortune. The matter might, indeed, be safely left to the operation of private interest but for the fact that in the present somewhat exceptional condition of affairs, when all eyes are turned to the Far East, time may become a question of importance. The first Pacific cable has not only the best chance of being successful in itself; it must also have the effect of delaying the construction of rival lines. If the British cable is to hold the field, it should be made without delay.

Stationary Motors on Trolley Circuits.

In enforcing the city ordinance relating to safe wiring, Mr. Ellicott, the city electrician of Chicago, has encountered the opposition of the Chicago General Railway company, which, it was claimed, was supplying 500-volt current to stationary motors from its grounded trolley circuits. This practice, as is generally known, is condemned as dangerous by the city authorities and insurance men, and it is stated that on several occasions the attention of the company was called to it by representatives of the city electrical department, with the warning that it must be stopped. A motor recently installed in a machine shop was the particular object of controversy. It was claimed that this motor was operated on the railroad company's grounded circuit, and the opportunity of inspecting it was demanded. This demand was opposed by the company, and in consequence Mr. Ellicott caused the cutting of the circuit leading to the machine shop from the trolley circuit. The company held that this was an unwarranted and unlawful act, and the city electrician was cited to appear in court to give a bond to preserve the peace. Mr. Ellicott's defense was undertaken by the city law department, and when the case came to a hearing before Judge Dunne it was decided that no offense had been committed. It seems, therefore, that the city is well within its rights in using extreme measures to prohibit the tempting but reprehensible practice of operating 500-volt motors on grounded circuits.

G. Willius, Jr., of St Paul will prepare plans for an electric-lighting plant for the city of West Superior, Wis.

CORRESPONDENCE.

New York Notes.

New York, May 16.—Apropos of the prominent part taken by the Edison Illuminating company in the electrical exhibition, it is interesting to note that from its six principal stations this company is supplying more than 7,500 customers, 370,000 incandescent and 5,000 arc lamps, and 20,600 horse power in electric motors; in all an equivalent of 726,000 lamps of 16 candle power each—the largest electric-lighting and power system in the world.

In the course of an instructive paper recently read before the Railroad Club of this city, George Gibbs gave some interesting facts about the electrical distribution of power in the Baldwin locomotive shops at Philadelphia. Electric power was first introduced in 1890, and now there are 215 motors, rated from two to 50 horse power each, and averaging nine horse power each for the entire number. The aggregate horse power in motors is 1,930. The total generator capacity installed is 700 horse power, and the daily average horse power at the switchboard is about 570, which is fairly constant throughout the day. The force of workmen needed to keep up all line repairs, inspecting and repairs on the 215 motors, and on ten arc dynamos and four power generators, consist of two men, with one-third of the time of another. One of these men alone keeps up repairs on armatures. The labor cost averages $6 per day, and the new material consumed in repairs is estimated to cost about $2 per day. The total labor and material cost per year is therefore about $2,500, or about four per cent. on the first cost of the plant. The plant is regarded as entirely satisfactory, and is being constantly extended.

The Holland, the submarine torpedo boat with the storage-battery equipment, is still undergoing test. The naval authorities are reported to be satisfied with the diving and steering capacity of the boat and her seaworthiness, but they desire to see the Whitehead torpedo-explosion tube tested with real ammunition. For this purpose a live torpedo with a practice head will be furnished by the government and will be discharged in the presence of a committee appointed by Secretary Long. The French government is said to be still trying to secure the Holland, but the owner naturally wishes to place her in the service of the United States.

A very unusual accident caused the death of William Claypool, a wireman employed by the Brooklyn Heights Railroad company, on Saturday afternoon. Mr. Claypool was conductor on a flat repair car. At the switch between First and Second avenues the trolley left the wire and caught in the frog overhead. The trolley wire above was pulled taut with the strain, and the trolley pole was also under a strain. Claypool went to the upright iron post which forms the base for the trolley pole on the flat car, and was trying to loosen the trolley from the frog, when suddenly the coiled spring on top of the iron post snapped, and a strand of it wrapped around Claypole's throat, his head being close to the spring at the time. The sharp end of the steel cut into Claypool's neck and slowly strangled him to death. He became unconscious before he was removed from the clutch of the broken spring, and died soon after the ambulance surgeon arrived. Claypool was 24 years old, lived at Fourth avenue and Ninety-fourth street, and had a wife and child. Stacom, the motorman, was arrested, although he does not appear to have been responsible for the accident. M. S.

Northwestern Notations.

Minneapolis, May 16.—The Citizens' Traction company of Oshkosh, Wis., has let the contract of the Falk Manufacturing company of Milwaukee, to extend its lines to Summer Park.

It is reported that H. M. Byllesby of St. Paul is working to secure the water power of the St. Louis River above Duluth, Minn., and develop power to be transmitted to Duluth and Superior by electricity.

A council committee of Perham, Minn., will investigate the matter of electric lights

Baker & Lord have been granted a franchise through the town of Farmington for their proposed electric line from Waupaca, Wis., to the Chain o' Lakes. C.

National Electric Light Convention, Chicago, June 7th, 8th and 9th.

The most popular line from Cincinnati, Louisville and all points South to Chicago is the Big Four Route via Indianapolis; magnificent sleeping cars and unequaled dining-car service. For maps, rates, etc., address E. O. McCormick, passenger traffic manager, Big Four Route, Cincinnati, O.

PERSONAL.

Mr. J. Appleton, the chief engineer of the construction department of the Electric Storage Battery company of Philadelphia, was in Chicago during the week, inspecting the work on the large battery now installed in the Adams street station of the Chicago Edison company.

Mr. E. B. Ellicott, the city electrician of Chicago, is still receiving the congratulations of his friends on the occasion of his recent marriage to Miss Minerva Ellsworth. Miss Ellsworth was a resident of Milwaukee, and she became Mrs. Ellicott in Plymouth Church at that city on the evening of April 26th. A large number of friends witnessed the ceremony. Mr. H. R. Hixson of Chicago was one of the ushers. Mr. and Mrs. Ellicott are now residing at the Chicago Beach Hotel.

ELECTRIC LIGHTING.

The city of Jacksonville, Fla., is to have increased electric-light facilities. It became apparent some months ago that the lighting plant was inadequate to supply the demand for lights, and it was then decided to double the capacity of the plant and also to introduce a day lighting-power service. These improvements are being pushed rapidly to completion, and it is expected that the new lights will be ready in a few days. Superintendent Patterson, in his electric-light report for 1897, recently submitted, stated that there had been an increase of receipts over those of 1896 of 22 per cent., and that the profits accruing to the plant during 1897 were $20,468.

ELECTRIC RAILWAYS.

Mr. McGann, the commissioner of public works of Chicago, has issued a permit to the Calumet Electric Street Railway company to build a trolley loop on Stony Island avenue, between Sixty-third and Sixty-fourth streets, across private property, in accordance with the ordinance passed by the council on March 28th.

The project for building an electric road from Rochester, N. Y., to Sodus Point has been revived, and there is some probability that the tracks will be laid shortly. Men who are interested in having the road built are Joseph C. Tone, Ira M. Luddington, Charles Van Voorhis and others. The prospective route into Rochester is by way of Clifford street to North St. Paul street.

The Rochester, N. Y., Railway company has discontinued selling six tickets for a quarter. At a meeting held May 10th Manager Nicholl called the attention of the directors to the fact that the receipts of the company were falling off, on account of the inroads made by the bicycle. A city ordinance requires the company to pay for the construction and repair of that portion of the street pavement between the rails and for two feet outside. This expense, it is estimated, will amount to about $75,000 this year.

The lease of the Rochester and Irondequoit Railway company's Summerville line to the Rochester, N. Y., Railway company is announced, the period of the lease being 10 years from April 15, 1898. The agreement is dated May 10th. The Rochester Railway company is to pay the lessor $8,000 a year in four installments of $2,000 each, the dates of payment being the 15th of June, July, August and September. If the earnings exceed $20,000 a year, 50 per cent of the excess amount will also be paid the lessor. The lease includes the Summerville ferry and the Windsor Beach picnic grounds, the lessor reserving the right to sell the grounds any time during the continuance of the lease.

TECHNICAL SCHOOLS.

The "Bulletin" of the College of Engineering and the Mechanic Arts of the University of Minnesota shows that during the school year now closing lectures on electrical subjects have been given by the following-named non-resident engineers: William I. Gray, Minneapolis, "Two hundred and twenty-volt Plants;" Edwin Reid, New York, "Underground Wires and Cables;" O. B. Playter, St. Paul, "Arrangement of Electric Plants." The courses of the college are open to all persons over 14 years of age free of all charge for instruction. The admission examinations are held on the last two days in August and the first two in September. George D. Shepardson is the professor of electrical engineering.

MISCELLANEOUS.

A new contract has been made between Robert G. Reid of Montreal and the government of Newfoundland, by which the former obtains complete control of all telegraph and telephone lines in the colony until April 15, 1904. Mr. Reid assumes all cost of maintenance and operation, and will receive all earnings and profits during that time, the government agreeing to pay $10,000 annually for service. He has also agreed to construct and operate an electric railroad in the town of St. John, or to see that it is done.

TRADE NEWS.

Mr. John Rice, who is so well and favorably known to the carbon consuming trade as the popular salesman of the National Carbon company of Cleveland, O., severed his connection with that company on the 15th instant, and has accepted a similar position with the Phœnix Carbon Manufacturing company of St. Louis. Mr. Rice's friends wish him every success in his new home in St Louis.

BUSINESS.

The Western Electric company claims for its alternating-current fan motors minimum attention, light weight, variable 'breeze, substantial construction, quiet running, pleasing appearance and high efficiency. The motors are of the induction type. The company's Bulletin 1 F describes them briefly.

The Boulder Electric Light company of Boulder, Colo., which has a number of Ball engines in satisfactory use, has recently ordered from the maker, the Ball Engine company, Erie, Pa., a 100 horse power engine arranged for direct connection to a 60-kilowatt General Electric machine. It is noted, also, that the Peruna Drug Manufacturing company Columbus, Ohio, has recently ordered from the Ball Engine company, Erie, Pa., and the Siemens & Halske Electric company, Chicago, two 150 horse power Ball engines direct-connected to 75-kilowatt generators, and one 225 horse power engine, direct-connected to a 150-kilowatt generator.

The Illinois Electric company has found it necessary to lease the entire basement at 239 Madison street, Chicago, 50 by 150 feet, with a large freight elevator in the rear. The company will carry in stock a large line of cross-arms, cross-arm braces, pins and brackets, lag screws, pole steps, etc., and will be able to fill orders on the day they are received.

Compartments on the New Pennsylvania Limited insure all the exclusiveness afforded by rooms in hotel or home. The finish of the compartments presents something entirely new in inlaid woods. The New Pennsylvania Limited leaves Chicago Union Station daily over the Pennsylvania Short Lines at 5:30 p. m. Space will be reserved upon application to H. R. Dering, assistant general passenger agent, 248 South Clark street, Chicago.

The new power station and car-house being erected by the Spencer, Warren and Brookfield Street Railway company at Brookfield, Mass., will have steel roof trusses and covering furnished by the Berlin Iron Bridge company of East Berlin, Conn. The dynamo and engine-room roofs of this building will be lined with the Berlin company's patent anti-condensation roof lining, which prevents the condensation of moisture from the underside of the roof covering, which, if it should collect and drop upon the machine beneath, would cause considerable damage.

ILLUSTRATED ELECTRICAL PATENT RECORD.

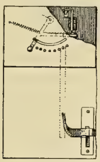
Issued May 10, 1898

603,623. Conduit Wiring Machine. William E. Cowan, Brooklyn, N. Y. Application filed August 27, 1897.

A guide section with runners, a rope-carrying section, a rod and clutches are utilized, whereby each of the sections may be rigidly attached to the interior of a conduit, and means provided whereby the sections may be alternately introduced within the conduit by means of the rod, and means whereby the clutches can be withdrawn from contact with the conduit.

603,624. Electric Railway. Eben C. Crocker, Bridgeport, Conn. Application filed September 17, 1897.

In an electric-railway system comprising a supply conductor, insulated power collecting sections, and a power collector carried by the car, the combination is claimed of the two series of magnets composed respectively of single magnets and pair magnets arranged opposite to each other and connected in separate branch circuits comprising one of the single magnets and two magnets selected from the pair magnets which immediately succeed and precede the single magnet in each instance, the insulated sections and the car rail with which the terminals of the circuits are connected, the armatures within the fields of the oppositely arranged magnets and carrying switches, the insulated contacts connected respectively with the power collecting sections and with the supply conductor, and the storage battery carried by the car and operating through the sections to energize the magnets whereby the switches are operated.



NO. 603,681.

603,625. Electric Railway. Eben C. Crocker and Edwin C. Howe, Bridgeport, Conn. Application filed September 17, 1897.

This electric-railway system comprises a supply conductor, insulated third-rail sections, and a power collector carried by the car, the two series of magnets comprising pairs of separate magnets arranged opposite each other, single magnets selected from each quarternate couplet of one series being connected in circuit with single magnets selected from alternate couplets of the other series intervening between the quarternate couplets, whereby branch circuits are formed, and connections with the conductor and sections through intermediate circuit closers and breakers operated by the magnets whereby the section having contact with the collector is in closed circuit while the sections immediately succeeding and preceding are in circuits capable of being closed by the collector.

603,630. Electric Arc Lamp. Frederick A. Gilbert, Brookline, and Emil O. Lundin, Beachmont, Mass. Application filed July 1, 1897.

A feed-controlling clutch including rotatable members to directly engage the carbon, rocking carriers for the members, brakes mounted on the carriers to prevent rotation of and press the members against the carbon, and an actuator to operate the carriers and control the brakes to thereby raise and lower the clutch bodily.

603,650. Automatic Electric Feed-water Regulator. Andrew E. Maccoun and John Noey, Braddock, Pa. Application filed December 3, 1897.

In a feed-water regulator for steam boilers a cylinder is connected with a boiler and a float is arranged in the cylinder upon one end of a lever; a vertically movable rod is secured to the other end of the lever and carrying a pair of contact points, and a standard is mounted upon the top of the cylinder carrying two pairs of contact points and having arms in which the rod is guided, the two solenoids having electrical connection with the two pairs of contact points and adapted to close or open a feed-water pipe valve.

603,672. Trolley Device for Electric-railway Cars. Louis E. Walkins, Springfield, Mass. Application filed April 14, 1897.

The combination is described with an overhead support or conduit having upper and lower ways or conductors of a trolley having a wheeled body running on the lower conductor or way and having a spring supported shoe to run with an upwardly bearing pressure on and along the upper conductor, the car having upright arms, one in advance of the other, each pivotally connected on the car for a fore-and-aft vibration, and each having adjacent its pivot an angular arm cushion above and below the arms and connections between the arms and the ends of the trolley body.

603,681. Throw-off Switch for Telephones. Nathan Fallek, San Francisco, Cal. Application filed August 17, 1897.

The combination with the pivotally attached switch lever of the spring, the ratchet-toothed bar, the sliding-dog, spring arm, pivoted lever, pivoted piece on the end of lever and the arm on the telephone hook having the inclines on the end to engage the inclines on the piece.

603,687. Electric Arc Lamp. John H. J. Haines, New York, N. Y. Application filed May 27, 1897.

The outer globe is supported on the annular base plate, the removable ring sustaining the globe, the arc-inclosing chamber mounted directly upon the plate over the opening therein, and a removable plate closing the opening and carrying the lower carbon holder.

603,696. Automatic Temperature Regulating Apparatus. Walter B. Loring, Worcester, Mass. Application filed November 5, 1896.

In combination with a heat-controlling damper a motor is operated by electricity, and a switch mechanism is adapted to be operated automatically by the revolution of the shaft to automatically cause the electric current to pass in one direction or the other through the field coil, to operate the armature and the shaft in one direction or the other, and move the damper.

603,705. Electric Incandescent Lamp. William J. Phelps, Chicago, Ill. Application filed September 7, 1897.

A constant-potential electric lamp comprising a vacuum bulb and two incandescing filaments, differing in resistance per unit of length, connected to receive current in series, but not otherwise or separately, the resistance of the filaments being such that one glows while the other serves as a relatively dark and dead resistance to modify the current.

603,709. Dynamo or Motor. Ferdinand Schwedtmann, St. Louis, Mo. Application filed October 23, 1897.

In a dynamo or motor, a suitable casing or housing for the field-magnet core cast in one piece, a laminated field-magnet core inserted in the casing from the bottom, and means for rigidly securing the core in the casing.

603,722. Electric Condenser. Charles S. Bradley, Avon, N. Y. Application filed July 29, 1897.

An electric condenser having its several plates separated by a fibrous insulating material, the pores and meshes of which are filled with stearate of lead.

603,745. Underground Conduit for Electric Conductors. Charles H. Sewall, Chicago, Ill. Application filed May 8, 1895.

A conduit duct for electrical conductors is described consisting of a smooth flat floor of indefinite length, the floor being a composite made by embedding a metallic frame in cement, concrete or other like plastic material, whereby the concrete acts as a resistance to compressive strain and the iron wires as resistance to tensile strain, and upon which are superimposed in sections inverted channels placed end to end.

603,815. Electro-therapeutic Apparatus. Gervaise G. Duke, Chicago, Ill. Application filed December 6, 1897.

Claim is made for the combination of an open-ended metallic casing provided with a jet orifice or orifices and with a marginal flange of insulating material, an outlet tube leading from the casing inside of the flange and a primary battery or other source of electrical supply, one terminal of which is electrically connected with the metallic casing, and the other terminal of which is provided with an electrode.

NO. 603,875.

603,849. Switch for Electric Motors. Frank E. Herdman, Winnetka, Ill. Application filed January 9, 1897.

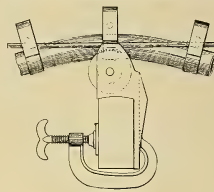
A switch is interposed between the source of current supply and the motor, one portion of the switch being adapted to make electrical connection with the source of current supply, the other portion being adapted to make electrical connection with the armature, and both portions of the switch being adapted to make electrical connection with the field, means to operate the switch to move the portion of the switch connecting with the current supply to and from central position without moving the other portion of the switch.

603,875. Electrical Apparatus for Schools. Melvin E. Crowell, Indianapolis, Ind. Application filed November 23, 1896.

This invention is described as apparatus for teaching electricity, comprising a base plate, a pillow block with a sleeve extending therefrom, an armature shaft mounted in such pillow block and sleeve, a driving pulley mounted on such shaft, an armature adapted to be removably mounted on such shaft, a lower pole-piece with a pair of posts extending therefrom, a pair of coils that fit over such posts and have suitable binding screws, an upper pole piece detachably secured to the posts on the lower pole piece, a commutator, commutator brushes removably mounted on the pillow block sleeve, an L-shaped bar with one end secured to a sleeve adapted to be carried loosely on the armature shaft and having a key at its free end and a binding screw at its other end, a clamping collar adapted to be mounted on the pillow block sleeve, a spiral spring surrounding the sleeve to which the L-shaped bar is attached and secured at one end to such collar and at the other end to the bar, an armature secured to the bar over the posts on the lower pole piece, and a post mounted in the base plate having two parallel arms, one above and one below such L-shaped bar, with a set-screw in the upper one, whereby a dynamo or telegraph sounder may be made.

603,882. Electric Lantern. Frederick G. W. J. Adams, London, England. Application filed April 24, 1897. Patented in England July 7, 1891, and in France April 18, 1893.

The battery casing consists of the case having integral therewith partitions and blocks at the bottom rim and grooves in front for receiving a sliding plate overlapping the cover, provided with metal strap with longitudinal recess, means for securing the cover to the case and a handle.



NO. 603,991.

603,886. Electrical Steering Apparatus. Harry O. F. Bindemann, Madrid, Spain. Application filed June 4, 1897.

Motors rotating in opposite directions and clutches for operatively connecting the rudder with either of the motors are combined with an axle or pivot adapted to be turned by the man at the wheel, a switch arm capable of a limited rotary movement relatively to the pivot, and having an inclined surface, a pin projecting from the pivot and engaging the inclined surface, a spring for keeping the pin against the inclined surface, contact devices arranged to be engaged by the switch arm and electrically connected to the clutches, and means for holding the rudder stationary after it has reached the desired position.

603,890. Primary Element with Regenerable Negative Electrode. Oskar Rothmund Edler von Burgwall and Leopold Ofenschüssl, Vienna, Austria-Hungary. Application filed December 9, 1896. Patented in Germany October 25, 1896, and in Austria November 9, 1896.

The process of manufacturing negative electrodes for primary batteries consisting in first preparing a peroxide plate of porous peroxide of lead on a lead frame, then freeing this plate of air and moisture, then impregnating the peroxide with a water soluble concentrated electrolyte and then partially drying the electrodes so that they present dry surfaces.

603,927. Means for Suspending Motors on Vehicles. Sidney H. Short, Cleveland, Ohio. Application filed February 25, 1898.

The combination with a wheeled vehicle of an alinement frame mounted on a driven axle, a motor journaled in the arms thereof, the weight of the motor being partially borne by springs interposed between the same and the alinement frame and by a rigid support extending to the truck frame and inelastically supported thereby.

603,991. Cable Stringer. Frank A. Cannon, Denver, Colo. Application filed December 3, 1897.

Suitable means are provided for supporting the cable and suspension wire; a bracket is adapted to be attached and a roller journaled on the bracket and adapted to engage the cable, the bracket being provided adjacent the roller with a ledge for supporting the suspension wire.

603,786. Electrically Controlled Switch. Edward M. Hewlett, Schenectady, N. Y. Application filed January 23, 1897.

The last claim is given: In a solenoid magnet, the combination of an inclosing casing and energizing coil, a cylindrical, straight-bored core, a removable cap having a central opening, the metal surrounding the opening having an increased cross section to provide a good magnetic circuit, a cylindrical movable core comprising two parts differing in their cross-section, and a piece of non-magnetic material arranged to guide the movable core within the stationary hollow core and prevent them from sticking.

Western Electrician.
EVERY SATURDAY.
Vol. XXII. CHICAGO, MAY 28, 1898. No. 22

Electrical Production of Ozone.

Since the abandonment of the plant for the electrical production of ozone at Marseilles, Ill., the experiments in this direction seem to have been carried on with much greater energy in England than in this country. The American plant was built with the idea of producing ozone to be sold for bleaching processes of all kinds, treating drinking waters and sewage, "ageing" spirits, separating sugar in sugar refining, as a preservative of milk, meat, etc., as a medicinal agent, and for many other useful purposes. The process of Ernst Fahrig was used, and while the plant seemed to be a scientific success, it did not meet the expectation of its promoters from a commercial point of view, and the work was discontinued several years ago.

The Fahrig process was described at some length in the Western Electrician of August 27, 1892. It consisted, essentially, of chemically producing oxygen, which was then passed through the electric discharge of a condenser attached to a transformer having a calculated electromotive force in the secondary winding of 40,000 volts. The ozone was produced by the action of the electrical discharge in the oxygen, and it was piped from the ozonizing generators to suitable receptacles.

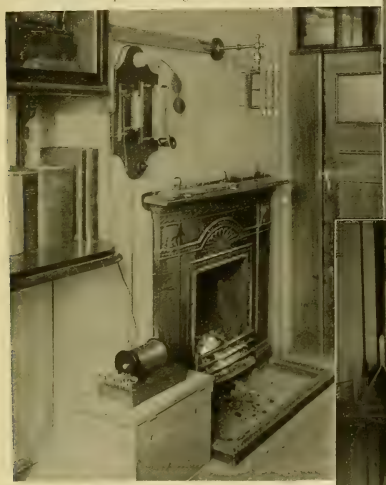


Fig. 1. Ozonizer and Inhaler for Ward Movement, with Ruhmkorff Coil and Leclanche Battery.

It is now well recognized that ozone is best made by the action of the electric spark on oxygen, although chemical processes were formerly employed to a limited extent. A number of scientists and engineers have worked in the direction of devising practical and efficient apparatus for producing the greatest amount of ozone from a given amount of electrical energy. Among them Emile Andreoli, in England, has been particularly active and persevering. He prepared a small book, entitled "Ozone, Its Commercial Production and its Applications," which was published in 1893, and he delivered a lecture on the same subject a little over a year ago, before the Society of Chemical Industry, which showed considerable advance. Mr. Andreoli has devised several forms of ozonizers. He is the technical manager of a London company which manufactures electrical ozone-generating machines, and several types of his interesting apparatus are illustrated herewith. He states that, theoretically, the expenditure of one electrical horse power hour should result in a kilogramme of ozone, but there is a wide divergence between theory and practice. He is now able to produce 130 grammes of ozone per kilowatt-hour in his latest ozonizer, and he is still seeking better results. The essential qualities of a good ozonizer, it is stated, are durability, easy construction and efficiency.

Mr. Andreoli has two classes of ozonizers—one in which the vacuum tube is an essential feature, and another, designed for larger sizes and the industrial production of ozone, consisting of grids formed of serrated wires and flat electrodes.

The first class is intended to be used principally for medical and sanitary purposes. The vacuum tube contains a metallic rod surrounded by an aluminum armature. When the current from a coil is used. A laboratory ozonizer, working with a small Miller & Wood transformer, is illustrated in Fig. 3.

A reproduction of a photograph of four of the ozonizing tubes, taken in a dark room, is given in Fig. 4. (This and succeeding pictures are on pages 306 to 309.) This set of open ozonizers is actuated by the current from a transformer which raises the current supplied from the street mains of the city of London Electric Lighting company from 100 volts to 4,000 volts.

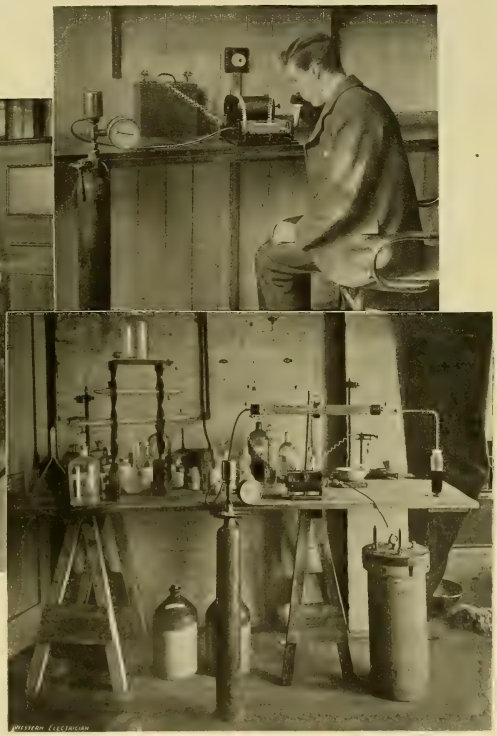

Fig. 2. Inhaler and Secondary Battery and Ruhmkorff Coil, used for Ozonizing Oxygen.
Fig. 3. Laboratory Ozonizer with Small Transformer.
ELECTRICAL PRODUCTION OF OZONE

Ruhmkorff coil or from a 3,000 to 5,000-volt transformer is sent through it, the coil becomes luminous and ozone is generated around it. These small ozonizers are intended for domestic or laboratory use. They are very compact and are said to be efficient. Fig. 1, in the large group of illustrations, shows an ozonizer of this class arranged with an inhaler for household or office use. The apparatus is fixed on a board and is worked with a Leclanche battery and a Ruhmkorff coil. Fig. 2 represents a modification of the same type. In this case, oxygen, and not atmospheric air, supplies the "raw material" for the ozone, which is used from an inhaler, as the picture clearly indicates. A storage battery here supplies the current, and a Ruhmkorff

Eminent physicians have prescribed ozone in many cases. Ozonized oxygen insufflated on wounds produces a remarkably beneficial action. Ulcers which had resisted every other treatment began to heal at once, the wounds rapidly filling with healthy tissue. In rooms, ozone purifies the air. Many consumptive people have been benefited by inhalation of ozonized oxygen; the essential point is not to administer ozone in extremis.

The second type of ozonizer devised by Mr. Andreoli is especially interesting from an industrial point of view. It consists, essentially, of grids formed of aluminum serrated wires and of flat aluminum electrodes. These are kept separated by sheets of glass, and the whole of the plates and

grids are held together by means of wooden clamps. The construction is extremely simple. No skilled labor is required either to make an installation or to superintend it. There cannot be any uncertainty or disappointment about the regular working of an installation, however large it may be, since if a given quantity of ozone is produced by a given surface of electrodes of an ozonizer with a given expenditure of electrical energy per hour, the number of similar ozonizers required to obtain a desired quantity of ozone in any time is readily obtained. These commercial ozonizers produce about 125 grammes of ozone per kilowatt, and are especially designed for industrial applications.

The special feature of this ozonizer is that the yield of ozone is increased very considerably. There is no circulation of water for cooling purposes. The generation of excessive heat by the electric effluvia on the dielectrics and electrodes is avoided. The electrodes of this form of ozonizer are point-bearing grids facing flat electrodes. The point-

FIG. 4. ELECTRICAL PRODUCTION OF OZONE.—LUMINOUS TUBES OF OZONIZER, PHOTOGRAPHED IN DARK ROOM.

bearing grids are composed of a number of serrated wires mounted on rods running through them and kept separated by washers. Fig. 5 shows one of the grids. There are 80 rows of serrated wires, each having 222 points, making a total of 17,760 points on both sides. This is sufficient to show how with moderately high frequency and a low tension it is possible to obtain a feebly luminous glow and discharge sufficient to bring about the formation of ozone without the production of nitrous compounds, so to speak, or rise of temperature, which would affect the yield of ozone. The flat electrodes are made of boards of wood, which are plane and true, and on the two sides of which are fixed thin sheets of aluminum. In this way perfectly even and plane plates at a moderate cost are obtained. Instead of metal sheets, layers of metal can be obtained by electroplating. An insulating material, such as glass, is used to separate the electrodes. This grid is two feet square. All the serrated wires should be parallel, although some are shown bent out of shape in the picture.

Fig. 6 represents one of the grids with a glass sheet behind it, which serves to separate the grid from the flat electrode. It is placed against a wooden frame, which is coated with some insulating material, and which serves to keep the dielectric plates and electrodes together. Next to this is a flat electrode which is made of wood and two thin sheets of aluminum. In Fig. 7 five grids and six flat electrodes are shown mounted in the frame. This arrangement gives 80 square feet of surface.

The following are the advantages claimed for this method of constructing and working open ozonizers for the production in a continuous process of large quantities of ozone in chambers and its supply from such reservoirs: (1) No separate air-tight box or receptacle being required for each set of electrodes or ozonizers, there is a saving in cost and labor. (2) The apparatus can be worked continuously because it cannot get out of order or seriously heat. (3) Only one inlet for the air and one outlet for the ozonized air are required for a number of open apparatuses simultaneously electrified in ozone chambers, while a complicated series of pipes is unavoidable when closed ozonizers are used. Therefore not only can the air be distributed at the same rate of velocity over the whole range of electrodes of the open ozonizers, but the cost of separate pipes for the inlet and outlet of each closed ozonizer is avoided. (4) The working of the whole of the ozonizers can be controlled, which is not possible when several ozonizers are enclosed in separate air-tight cases. (5) In case of accident, or in case cleaning is required, the apparatus can be quickly taken to pieces and put together again. Any desirable number of ozonizers may be arranged in a chamber, according to the size of the chamber, or several ozone chambers may be used, each containing a number of open ozonizers, according to the electric current which is used for each set of electrodes.

Examples of the "open" ozonizers are shown in Figs. 8 and 9. The former represents a small ozone generator having 48 square feet of surface, and the latter an ozonizer having dimensions of 60 by 40 by 40 inches and 650 square feet of surface. The large generator is enclosed in a box and is supplied with current through a Crompton transformer.

Ozone installations consist of an alternating-current dynamo or other source of alternating current, one or more step-up transformers, and of one or several ozonizers, according to the quantity of ozone it is required to produce. The cost of a 500-watt installation, capable of yielding about 60 grammes of ozone per hour, is placed by Mr. Andreoli at about $700, including also an ozone chamber, measuring instruments, cables, switches, etc.

The commercial uses of ozone, if it can be produced cheaply in quantity, are manifold. It is an oxidizing agent par excellence, and is valuable in the many industries where oxidation is a feature. It contains nothing but oxygen, and so can be used for oxidation without danger of adulterating or injuring the substance to which it is applied. The only question is the commercial practicability of the production, and Mr. Andreoli claims to have made satisfactory progress in this direction. In addition to the applications mentioned in the first paragraph of this article, it is stated that ozone is adapted for drying and deodorizing fish and other oils, for seasoning wood and for purifying starch and edible fats. The sterilization of impure water is also a very important use of the disinfecting properties of ozone. On another page of this issue of the Western Electrician is an article describing the treatment of the water of the river Seine.

American Institute of Electrical Engineers.

At the annual meeting of the Institute last week a membership of 1,098 was reported and a treasurer's balance of $1,453.09. It was stated that the important committee on the standardization of dynamos, motors and transformers, consisting of F. B. Crocker, Cary T. Hutchinson, A. E. Kennelly, J. W. Lieb, Jr., C. P. Steinmetz, L. B. Stillwell and

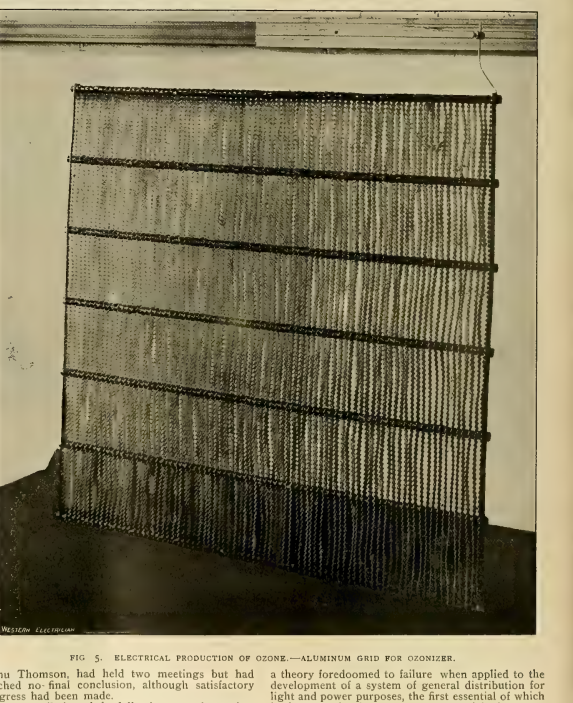

FIG 5. ELECTRICAL PRODUCTION OF OZONE.—ALUMINUM GRID FOR OZONIZER.

Elihu Thomson, had held two meetings but had reached no final conclusion, although satisfactory progress had been made.

The council elected the following-named associate members: F. L. Cadon, Washington, Ind.; Thomas Dempster, Schenectady, N. Y.; Paul Letheule (electrical engineer commissioned by French government), Schenectady, N. Y.; Livingston Johnston, Jr., Islip, N. Y.; Howard Joslyn, Seattle, Wash.; James J. Mahony, New York, N. Y.; Irving A. Taylor, Brooklyn, N. Y.; Wallace Rupert Turnbull, East Orange, N. J.; James H. Winfield, New Glasgow, N. S.; Fred. W. Wood, Los Angeles, Cal.

The following-named associate members were transferred to membership: Edward Burch, Minneapolis, Minn.; G. A. Redman, Rochester, N. Y.; L. S. Boggs, Ogden, Utah; Gustave J. Fischer, Sydney, N. S. W.; James B. Scott, Baltimore, Md.

Development of the Central Station.[1]

By Samuel Insull.

Part I.

When requested a short time ago by the chief of the electrical department of this university to deliver a lecture on some subject connected with central-station work, I must confess to having had some misgivings in accepting the honor to appear before you this evening, remembering the disadvantages that a commercial man invariably feels in discussing technical matters before those having had technical training, but then I remembered that even within my own time (and I think I can still claim to be a young man) very little was known of the general distribution of electrical energy from a central station, and when I recalled that so recently as the early '80's it was necessarily the rule for "guessing to be a substitute for mathematics" (to use the words of the great pioneer in central-station work), my misgivings were inclined to disappear, and I felt encouraged to talk to you on the development of the central station from the point of view of my own experience in following this, the latest of the great industrial developments of the wonderful era in which we live.

In referring to the development of the central station, it would hardly seem necessary to go at length into the history of the business, the origin of which probably dates from the work of the early experimenters whose efforts were directed to the perfection of series arc lighting. While their work is entitled to the greatest possible praise, it should be remembered that the theory on which they worked, namely, constant current and varying potential, is a theory foredoomed to failure when applied to the development of a system of general distribution for light and power purposes, the first essential of which is the necessity for a constant potential, the quantity of current varying in accordance with the demands made by those desiring to use the energy, whether for light or power purposes. Nor does it seem to me a matter very pertinent to the present occasion to trace the rival claims as to priority of invention of the early experimenters on incandescents lamps. Which of them was the first to produce a lamp that could be brought to a state of incandescence by means of the electric current is hardly within the scope of our inquiry. Probably all of them, groping in the dark (now and then illumined by the flashes of light emitted from their experi-

1. Lecture delivered before the Electrical Engineering Department of Purdue University, Lafayette, Ind., May 17, 1898.

mental glow lamps), contributed in a more or less degree to the perfection of the incandescent lamp as now in every-day use; but so far as their contributing much that is substantial, in the development of a system of central-station distribution, it is probable that, up to the year 1880, there was but one man who realized that in solving the great problem of electrical distribution the perfection of a filament of high resistance, which, placed in a hermetically sealed glass globe from which the air had been exhausted and connected in multiple arc across an electric circuit, was the first necessity to the distribution of electric energy in our cities from a central-station system.

In Mr. Edison's application for a United States patent on a system of electrical distribution filed at Washington on February 5, 1880, he says:

The translating devices for each house may be either for light or power, or both. For light, the electric lamp, consisting of an incandescing material hermetically sealed in glass (shown in other applications made by me) is preferred. This lamp is made of a high resistance in comparison with that of any electric lamps which, to my knowledge, have been proposed. In lights heretofore proposed the endeavor seems to have been to lessen the resistance of the carbon, none having been suggested of higher resistance than, say, 10 ohms; but I have discovered that a very much higher resistance, say 100 ohms, must be used, in order that a number may be economically and successfully used in a system.

The question of the high resistance of the translating device was the first stepping-stone to success. Everybody prior to Edison had aimed at getting a low-resistance lamp, I presume on the theory that the less the resistance of one the less the resistance of the whole series. He struck out on new lines. A high-resistance lamp was naturally followed by a multiple-arc system.

In writing of the necessity of a high-resistance lamp, the applicant for the patent had in mind that a system of electrical distribution could be used at the same time not only for lighting but for power purposes, if the motors were properly constructed, and this is evidenced by the next paragraph in his application, which states:

The motors should be so constructed that each, with a constant flow or pressure of current, will give the exact power required. This requires that each motor should be wound with finer or coarser wire, and into more or less convolutions, which determine the maximum effect of the motor.

If you will search the files of the daily and technical journals and the proceedings of various scientific societies on both sides of the Atlantic from the summer of 1878 to and including the year 1882, you will find that the great obstacles in the way of an economical system of central-station distribution were the difficulties of producing a lamp that would last—one requiring only a minimum of current—and a system of electrical distribution requiring a minimum of capital, so as to enable electricity to compete with then existing methods of illumination and power. Professor Henry Morton, on December 28, 1879, says in the New York Times:

The first difficulty of all is the production of a lamp which shall be thoroughly reliable and neither complicated nor expensive. All attempts in the present lamp in this direction are acknowledged to be failures, and, as I have pointed out, there does

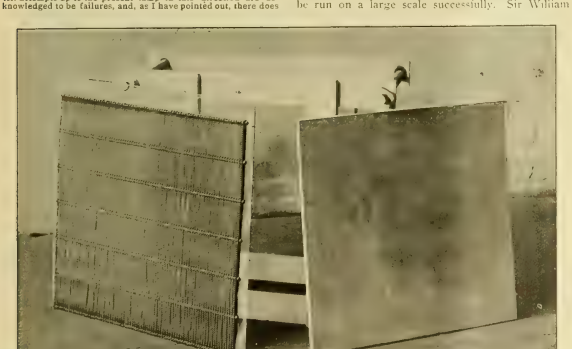

FIG 6 ELECTRICAL PRODUCTION OF OZONE.—FRAME, GLASS DIELECTRIC, SERRATED WIRE ELECTRODE AND FLAT ELECTRODE.

not seem to be any novelty such as would authorize us to hope for better success than the present one. The next difficulty is the economical production of small lights by electricity. This is what is commonly meant by the phrase "dividing the electric light." Up to the present time, and including Mr. Edison's latest experiments, it appears that this involves an immense loss of efficiency.

Next come the difficulty of distributing on any large scale the immense electric current which would be needed, and to provide for their equal action at different points under varying conditions of the number of lights used.

Again Mr. Conrad Cooke, giving evidence before the British parliamentary commisson in 1879, in answer to the question, "Supposing that the occupier of one house wished to put out his lights, how would this be effected?" replied:

In that case, if you throw out a lamp or throw out a house, you must throw into the circuit a resistance exactly equal to what you cut out. If you do not do that, you will affect every lamp in the series and the machine as well. If you put out your lights by breaking the circuit, you put out every light in the series.

In answer to another question at the same parliamentary inquiry, Mr. Cooke said (referring to Dr. Siemens, who had been named in the question):

His nephew told me himself that he had seen, I think, over 200 lamps on one of Edison's circuits.

And Mr. Cooke added:

I must say I should like to see it myself, and that is all I can say.

It is quite evident from this that Conrad Cooke, very well known in England as a prolific writer on the subject of electrical experiments, had in mind, in

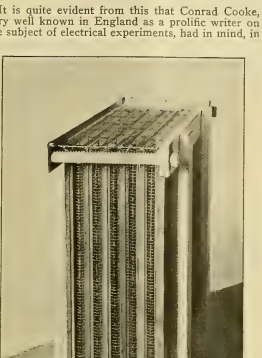

FIG 7. ELECTRICAL PRODUCTION OF OZONE.—GRIDS AND ELECTRODES MOUNTED IN FRAME.

1879, nothing better than the series system; that is, a number of incandescent lamps run precisely the same as arc lamps; or, to put it another way, his idea of the electric-lighting system was a varying potential and a constant current, which could never be run on a large scale successfully. Sir William Thomson (Lord Kelvin), referring to the same parliamentary inquiry of 1879, says:

I had not myself, at that time, any idea leading toward the practical realization of any such distribution of conductors and placing the lights as outlined in the Edison multiple arc and feeder system.

Evidently Mr. Swan, the English inventor, had no idea of the feeder system as late as October, 1880, as in a lecture before the Literary and Philosophical Society of Newcastle, England, at that time, he said:

The only way of avoiding this waste of energy, without abandoning the idea of small units of light, would be either to employ enormously thick conductors, or have every limited area supplied from one source.

Mr. Swan was referring to Mr. Edison's plain multiple-arc system, as set forth in his application of February, 1880. The last eight words of this quotation prove that Mr. Swan did not then know of Mr. Edison's feeder system, application for patent on which was made on the 9th of August, 1880, and was patented in England on the 24th of September of the same year. It would seem that even in 1882 Mr. Swan, who himself at that time must have been informed as to Mr. Edison's invention of the feeder system, could not have appreciated the possibilities of such a system, as, in a paper communicated to the British Association at Southampton in August of that year, he stated:

The only escape from that limitation (extent of distribution) lay in having secondary batteries at stations or in houses, and in these batteries being charged in series, and fed by currents of higher tension, the principle still holding of multiple arc, not from the central station, but from the subsidiary ones from which the batteries are charged. Once imagine the possibility of these secondary batteries being kept at a perfectly constant condition of charge by some automatic arrangement, and we might look to that as a means of escaping from the difficulties of wide distribution.

Again we find that Dr. C. W. Siemens, before the Society of Arts in London, on the 15th of November, 1882, said that he thought

It would be possible to establish electrical mains in the shape of copper rods of great thickness, with branches leading from them in all directions, though he was himself decidedly averse to such a plan. He said he would limit the area of the densely populated district to one quarter of a square mile, notwithstanding other individuals of high standing in electrical circles held that areas of from one to four square miles could be worked to advantage.

Dr. Siemens went on to say:

In considering the proper size of conductors, two principal factors have to be taken into account: First, the charge for interest and depreciation on the original cost of a unit length of the conductor, and secondly, the cost of the electrical energy lost through the resistance of a unit of length. The sum of these two, which may be regarded as the cost of the conveyance of electricity, is clearly least, as Sir William Thomson pointed out some time ago, when the two components are equal. This, then, is the principle on which the size of a conductor should be determined.

Lord Kelvin, commenting on Dr. Siemens' remarks of November 15, 1882, before a commission taking evidence with relation to the Edison feeder patent, said:

There is not a word here of the necessity to secure against too great drop of electric potential between the dynamo and the lamps, or too great differences of drop between the different lamps of the system, and the narrow limitation of the area insisted upon shows that Dr. Siemens had no idea of Edison's solution of the problem, and thought only of overcoming the difficulty by enormously massive copper conductors with branches diverging from them to the points of consumption. From his earliest commencement as an inventor and engineer, Siemens had been occupied with water and gas. His first invention was a water-meter, and it is not probable that anyone in the years 1879-80 knew better than he did of the difficulties met with in the distribution of water and gas, and of the methods which had been practically used or proposed for overcoming them.

Again referring to this same subject, Sir William Thomson said:

About that time, or a little later, one of our first electrical engineers, Mr. Crompton, who has, in fact, more than any one to introduce successfully and on a large scale lighting from a central station in London, found that he was obliged to use larger copper conductors than would be required merely in accordance with my principle for economy, in order to avoid so great a drop in potential as would be inconsistent with the good working of the lamps. At that time he had no idea of the feeder system, which he has since adopted with marked success in the Kensington-Knightsbridge electric lighting. Siemens' solution was not augmenting the size of the conductors above that calculated from the economic law, but to limit the size of the station supplied. Neither this nor the solution first proposed by Crompton is satisfactory in respect to the practical demands for the electric lighting of towns. Edison's feeder system is now universally admitted to be satisfactory to a very remarkable degree. I am asked why did not some one else invent it. The only answer to to this, the last part of the question, that I can think of, is that no one else was Edison.

I personally well remember Sir William Thomson's visit to the Pearl street station in New York, in 1884, when he saw the Edison feeder system first in operation, and the great interest that he exhibited in studying it, and his admiration for the work accomplished by Mr. Edison in this connection.

I have thought it necessary to thus quote at length some of the leading English authorities on electrical matters, as I thought it would be better, in claiming for an American the conception of the true basis of electrical distribution for light and power purposes, to give you the opinion and views on the matter of distribution of our "kith beyond the sea" rather than to quote the views of American scientists, who might possibly be considered more partial to the work of their own countryman.

It is often said that the principles of constant-potential multiple-arc distribution and the use of feeders to maintain an equal and economical distribution of pressure are self-evident propositions, following the lines of gas and water distribution; but when you have such high authorities as Conrad Cooke in 1879 failing to recognize any of these necessities, of Mr. Swan in 1880 only recognizing the principles of multiple arc, and in 1882 failing to recognize the importance and far reaching results of the feeder system, and Dr. Siemens as late as November, 1882, two months after a central station was in operation in New York city, adopting almost the same views as Mr. Swan, you cannot wonder at Lord Kelvin answering the question as to why someone else did not invent the feeder system by saying: "The only answer to this, that I can think of, is that no one else was Edison."

It would seem to me, with such authorities, that it is not unreasonable to claim that the development of the central station and distribution system connected therewith dates from Mr. Edison's work at Menlo Park. Mr. Edison had been engaged during the early 70's, first as a telegraph operator in the Western Union service, and later working on the gold indicators in the gold room in New street, New York, during the stirring period of speculation in

the precious metal which culminated on Black Friday in 1873. Professor C. C. Law, now connected with the University of Missouri, had, I believe, charge of the indicating instruments, and it is a matter of some interest to record the fact that the first work Mr. Edison did of an inventive character which yielded him a financial return was in connection with and while he was at work on the gold indicators in question. Subsequently he was employed in the interest of what is now the Western Union Telegraph company, in improving the now universally-used stock ticker. This work was followed by brilliant and successful work in connection with the duplex and quadruplex and automatic systems of telegraphy, and the invention of the phonograph and that part of the telephone now generally used for transmitting purposes, and known as the carbon transmitter. His attention to the possibilities of what is popularly called the subdivision of the electric light was probably the result of a visit he paid to Mr. William Wallace at Ansonia in the fall of 1878, where he saw some experiments on a dynamo machines, and on his return to Menlo Park he started his experiments on a system of electric light and power, which culminated in the successful starting of the first central station, in the lower portion of New York city in September, 1882.

The public interest aroused in his work and the controversy as to whether it was possible for him to achieve anything that would be of commercial value are evidenced by the constant reference to the matter in the public press in 1878, 1879 and 1880, resulting in a panic in gas securities in London in 1878 and in New York in 1879. Probably the work of no inventor was more generally discussed on both sides of the Atlantic by laymen and technical authorities alike than was that of Mr. Edison on his electric-lighting and power system. All kinds of comparisons were made as to the difference between the cost of gas and the cost of electricity. It was claimed by many that Mr. Edison could not possibly be considered as having succeeded in his work unless he could produce an illuminant that would compete commercially with gas. They lost sight of the fact that the characters of the two illuminants were entirely different, and that there was no more reason for supposing that, if electricity were more expensive than gas, the cost would be a barrier to its use, any more than there is reason for supposing that gas should be considered a commercial failure because the poorest classes find it cheaper to use tallow dips. The probable reason for scientists and electricians doubting the possibility of a successful electric-lighting system being produced was that all previous experimenting on incandescent lamps had been, as I have already stated, aiming at producing a lamp of the lowest possible resistance, and consequently requiring the greatest possible amount of current, these lamps being run in series, whereas Mr. Edison, at a comparatively early stage of his work, realized that the first essential was a lamp of high resistance, and that the only way of approximating an even distribution of pressure was to run these lamps in multiple arc. Hence his application for a patent on a lamp with a high-resistance filament, under date of November 4, 1879, and his application on multiple-arc distribution in February, 1880. It was then but a short time before he realized that, although experimentally by this might give him even pressure, the expense of the copper in his distribution system would be too great, owing to the necessity of increasing the size of his copper as he got farther and farther from the point of generation. The result was that in March, 1880, he applied for his patent on a system of feeders to supply his system of mains at various points throughout the system, the effect being a compact system with current flowing in all directions from the central point of generation through feeders, by means of which even pressure could be maintained throughout a considerable area.

A still further step made by Mr. Edison was the realization that nothing very reliable in the way of a distribution system in large cities could be maintained unless the work was placed underground, and, as a result of his work of a little over two years, we find that, in the early winter of 1880, Edison had a central-station system experimentally at work at Menlo Park, N. J., having an underground two-wire system, with the homes of himself and his staff electrically illumined by incandescent lamps, motors at work in his laboratory, and, in fact, all of the essential features of what is to-day now so common from the largest cities to the smallest villages throughout the whole civilized world.

It was but a short time after the starting of the first central station, in New York that Mr. Edison found himself looking for some more economical methods of distribution; and I well remember his first experiments on the three-wire system, when, at his shop in Goerck street, New York, he placed a third brush on the neutral point of the commutator of a small bi-polar Edison dynamo and demonstrated the practicability of the three-wire system.

At the same time that Edison was working on the three-wire system experimentally in New York, Dr. John Hopkinson was probably figuring out the same thing in England, and Werner von Siemens was engaged in similar work in Germany. The records of the United States, English and German patent offices bear witness to the fact that these three men accomplished about the same results at about the same time, and, as a consequence, between 60 and 70 per cent. of the investment in copper was saved.

It is not my wish to address you on the scientific or technical side of central-station development. I have thought it necessary to go at length into the early work of the art more for the purpose of giving you some idea of the position to which Mr. Edison is entitled as the father of central-station work. My limited knowledge of the technique of the business would not permit me, even if I wished, to discuss the details of his early work, or of the early work of other experimenters; but I assure you that daily familiarity with the operation of one of the largest central stations in this country gives me a higher and higher appreciation of the simplicity and thoroughness and adaptability to all purposes of electrical distribution of the great work accomplished by the "Wizard of Menlo Park."

As a result of the experiments at Menlo Park, Mr. Edison, early in the winter of 1880, started to get together the necessary data for the establishment of a central-station and distributing system in New York, in the district bounded by Wall street on the south, Nassau street on the west, Peck's slip on the north, and South street on the east, a territory covering about 2,000 feet square. He had each house thoroughly canvassed to show the number of lights in use, the number of hoistways and elevators, and the horse power of the engines running machinery. You will find on the walls around us the blueprints of these original canvasses.[1] On one blueprint you will find an enumeration of the power in use in that district and on the other blue-print a record of the lights there used. As a result of this

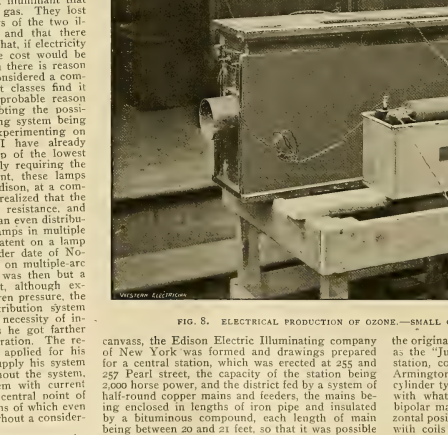

FIG. 8. ELECTRICAL PRODUCTION OF OZONE.—SMALL OZONIZER AND TRANSFORMER.

canvass, the Edison Electric Illuminating company of New York was formed and drawings prepared for a central station, which was erected at 255 and 257 Pearl street, the capacity of the station being 2,000 horse power, and the district fed by a system of half-round copper mains and feeders, the mains being enclosed in lengths of iron pipe and insulated by a bituminous compound, each length of main being between 20 and 21 feet, so that it was possible to take off a service at each house.

Time will not permit me to go into the details of construction of this, the first central distribution system. You will see by referring to the outline drawings of the station which I have with me, that the boilers were placed down below and were of the horizontal water-tube type, made by Babcock & Wilcox, carrying a pressure of 125 pounds, the steam machinery and dynamos being of the direct-connected type and placed on a steel structure not dissimilar to that of some portions of the elevated-railroad structure in New York.

Great care was taken in figuring out the system of mains and feeders, an immense plot of the district being represented by a series of resistances, showing in miniature the probable consumption of current in the various parts of the district. It should be remembered that the path to be followed was practically unknown, that electrical distribution on a large scale was as much of a hidden secret as an unexplored continent, and the remarkable thing is that this first experimental system was a practical success, and a return on the money invested was being earned before electricians at home and abroad would recognize the success of the undertaking. It is but natural that many devices were used which were subsequently absolutely discarded. For instance, an elaborate system of resistances placed in series with the feeders was employed for maintaining an even pressure, entailing a considerable waste of energy. The lamp employed was not more than one-half as efficient as that used to-day, while the cost of manufacture was many times greater, and it had not one-quarter of the life of the present commercial incandescent lamp.

It might be well to pause for a moment and picture the condition of the art at that time. I refer to the winter of 1880. The plans for the central station were completed; the details of construction of the conductors in the street were all on paper; the dynamos and electrical instruments had no existence except on the draughting-board; practically nothing was known of modern methods of insulation or house wiring; the socket and switch in use to-day had not been thought of; the miscellaneous devices now considered necessary in connection with house-wiring had not been considered. In addition to the development of the system and its installation, manufacturing establishments had to be created in which to manufacture the first material needed, and Mr. Edison and his corps of assistants had to abandon the experiments of the laboratory and the designing of the draughting-room to equip and manage shops in which to manufacture the apparatus necessary, from the generator to the lamp. Others have followed the beaten track, others have improved upon the methods employed, but the conception of the system, the perfecting of the original apparatus, its manufacture, its installation and its early operation were all borne by an enthusiastic but small band of workers having an almost idolatrous belief in their chief as the pioneer of this great industry.

I have brought with me to-night a photograph of the original direct-connected steam generator, known as the "Jumbo" machine, used in the Pearl street station, composed of an engine manufactured by Armington & Sims of Providence, R. I., of the single cylinder type, running at a speed of 350 revolutions, with what is practically the old form of Edison bipolar machine changed from a vertical to a horizontal position, the armature, instead of being wound with coils of wire, being built up of copper disks and bars. If you will glance from this to the picture of a modern central-station unit composed of a compound, triple or quadruple expansion engine, with a multipolar dynamo connected directly on the engine shaft, you will find that the same broad engineering idea is alike apparent in the earliest and latest central-station unit. The improvements in dynamo manufacture have enabled us to use lower-speed engines, but the broad principle of direct connection is alike the same in both. That we should come back to exactly what Mr. Edison used in the earliest central-station work is no mean tribute to him as an engineering authority.

The delay which necessarily occurs in carrying every new enterprise to a financial success acted as a wet blanket on central-station development. Efforts were made to cheapen construction when it was found that capitalists in large cities were unprepared to risk their money in the enterprise. The apparatus was adapted to the requirements of smaller communities, and, as a result, a number of small stations were established throughout the country, especially in Pennsylvania, Ohio and Massachusetts. The development of the central-station business for several years was confined to this class of work. The service was far from reliable, owing mainly to the necessity of doing the cheapest possible engineering and construction in order to meet the necessities of the slim exchequers of those who were bold enough to embark their capital in this business; but the Pearl street station, started on September 5, 1882,

[1] The curves and charts are not reproduced here as they form part of the confidential records of the Chicago Edison company.

with 5,500 lamps, rapidly developed, and in the fourteenth month of continuous running had 508 customers wired for 12,732 lamps. Comparatively little work was done in central-station lighting in Europe. A small station was started in Dijon, France, in June, 1883, and in the same year an installation was made in Santiago, Chile; in Milan, Italy; on Holborn viaduct, London, and in Manchester.

The success of the Pearl street station resulted in the extension of the New York system and the building of two stations uptown in New York, one in Twenty-sixth street and the other in Thirty-ninth street. This was followed by a station in Boston and another in Brooklyn. In 1887 the building of the first station in Chicago was started, the average load, as shown by the composite ampere curves of that station, which I have with me, being not much over 500 amperes for the year 1888. These latter stations, the two in New York, the one in Boston and the one in Chicago, were equipped with high-speed engines belted to Edison bipolar dynamos of the Siemens armature type, in some cases the engines and dynamos being on the same

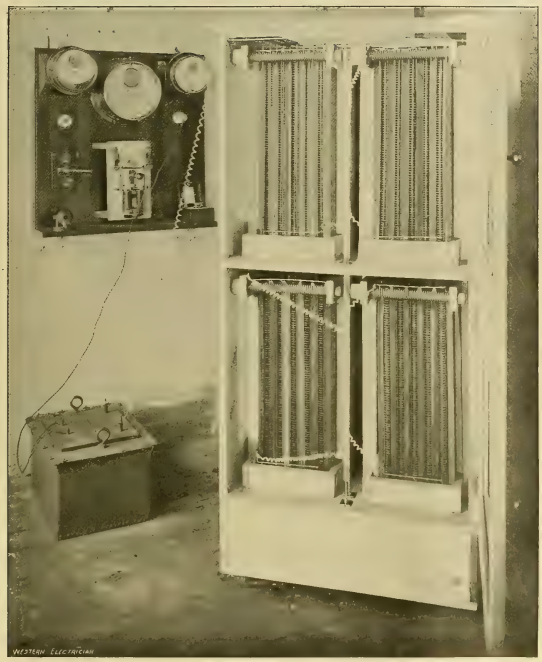

FIG. 9. ELECTRICAL PRODUCTION OF OZONE.—LARGE OZONIZER IN BOX.

floor, in other cases the engines being belted to the dynamos on the floor above. Numerous other stations were started, so that by 1890 upwards of 60 cities were equipped with the direct-current low-tension system, all of which, and numerous others, are to-day so remunerative that their securities are considered among the most desirable local investments, especially in cities of the first and second rank.

The success of the low-tension system was followed by the introduction of the alternating system, using high-potential primaries, with the converters at each house, reducing, as a rule, from 1,000 down to either 50 or 100 volts. I am not familiar with the early alternating work, and had not at my disposal sufficient time in preparing my notes to go at any length into an investigation of this branch of the subject; nor do I think that any particular advantage could have been served by my doing so, as it has become generally recognized that the early alternating work with a house-to-house converter system, while it undoubtedly helped central-station development at the time, proved very uneconomical in operation and expensive in investment, when the cost of converters is added to the cost of distribution. The large alternating stations in this country have so clearly demonstrated this that their responsible managers have, within the last few years, done everything possible, by the adoption of block converters and three-wire secondary circuits, to bring their systems as close as they could in practice to the low-tension direct-current distribution system. I do not want to be understood as undervaluing the position of the alternating current in central-station work. It has its place, but to my mind its position is a false one when it is used for house-to-house distribution with converters for each customer. The success of the oldest stations in this country, and the demonstration of the possibilities of covering areas of several miles in extent by the use of the three-wire system, resulted in much capital going into the business. One of the earliest stations of a really modern type installed on either side of the Atlantic was built by the Berlin Electricity Works. The engineers of that station, while recognizing the high value of the distributing system, went back to Edison's original scheme of a compact direct-connected steam and electric generator, but with dynamos of the multipolar type designed and built by Siemens & Halske of Berlin, the engines being of vertical marine type.

This was followed by the projecting in New York of the present Duane street station, employing boilers of 200 pounds pressure, triple and quadruple-expansion engines of the marine type, and direct-connected multipolar dynamos. Almost immediately thereafter, the station in Atlantic avenue, Boston, somewhat on the same general design, so far as contents are concerned, was erected. In 1891 a small station, but on the same lines, was projected for San Francisco, and in 1892 the present Harrison street station of the Chicago Edison company was designed, and, benefiting by the experience of Berlin, New York and Boston, this station produces electric current for lighting purposes probably cheaper than any station of a similar size anywhere in this country.

It is not necessary for me to go into detail in explanation of the modern central station. You are all doubtless quite familiar with the general design, but if you will examine the detail drawings of the Harrison street station, which I have brought with me, you will find that every effort has been made

[*Continued on page 316.*]

Purification and Sterilization of Wat by Ozone.

In 1894 the Municipal Council of Paris offered a prize for the best process for purifying and sterilizing the water of the river Seine. No less than 148 methods were presented, no one of which was accepted as satisfactory. The various processes included thermic, chemical and mechanical suggestions. Filtration through sand, charcoal, cellulose, asbestos and kaolin, and chemical treatment with lime, salts of iron, aluminum, etc., were proposed. An electro-chemical method promises, however, to solve the vexed question in an economical and perfect manner.

Experiments have shown that ozone has a marked destructive power over microscopic organisms in water, provided the water is not too largely filled with organic substances.

Baron Tindal of Oudshoorn (Holland) has experimented extensively upon this matter since 1891. The results have been so satisfactory that they have led to the erection of a large installation at Saint Maur, which daily treats 20,000 cubic meters of the Seine water, at a minimum cost of 0.025 of a franc for each cubic meter.

At the Brussels Exposition an exhibit was made of the system, which included an alternate-current dynamo which was made to produce a current of 30 amperes at 75 volts. This current was raised by a step-up transformer to 35,000 volts, one terminal of the circuit being grounded, the other leading to the ozonizers. A second transformer here raised the electromotive force to 100,000 volts. Insulation was now difficult of maintenance. For this purpose the secondary circuit comprises 10 bobbins in series of 10,000 volts each, supported by glass and wood, and separated 10 centimeters apart. There is an

Fig. 1.

Fig. 2.

Fig. 3.

PURIFICATION AND STERILIZATION OF WATER BY OZONE.

air space of 20 centimeters between the secondary and the primary, the latter being within the former. The magnetic circuit, composed of a bundle of soft iron plates, is also carefully separated from the rest of the apparatus.

The chambers for ozonization are in the form of a rectangular frame 25 centimeters wide, 35 centimeters high by 60 long. Their purpose is to provide a resistance sufficiently high to prevent sparking and insure a silent discharge. Each tube ends in the interior of this case or chamber at a metal block composed of several leaves of platinum bound together (Fig. 1), which forms one electrode. The other electrode consists of a couple of gilded copper plates (Fig. 2) lying against the side of the case, and thence connected to earth.

When the current passes between the interior plates of this case it appears as a violet band, with rays slightly divergent and of a deeper color. Fig. 3 represents the five chambers.

The air to be treated is drawn by a pump through a dry cotton-batting filter to cleanse it of dust, then through calcium chloride to desiccate it, then further manipulated with sulphuric acid. From here it passes into the first ozonizer through openings in one of its sides, thence into the second and on through the series of five chambers.

As it is very essential that the air be kept cool as well as dry, a coil is placed between each two cases, through which a current of air is constantly circulating at a temperature reduced to —25° Centigrade by means of an ammonia machine. The air is thus cooled in its passage from one case to the next.

Leaving the last ozonizer, the air enters the sterilizing columns, which are of stone or enameled iron, provided with false bottoms pierced with holes, by which the ozonized air is ejected in the form of bubbles, and is also washed by ascending spray.

A second system consists in converting the water into cold vapor in the ozone chamber. This process does not require so high a pressure as the former, and as it costs less to work at a lower pressure, there is probably a point where economy would be greatest between two extremes. L'Electricien is the authority for the facts in this brief article.

Everything is now in readiness for the reception of members of the National Electric Light association, the committee representing the Chicago electrical interests having completed its preparations for the convention which is to assemble in this city on June 7th.

It is expected that this gathering will include more central-station managers and more practical electrical engineers than have ever before attended a meeting of that body. The convention will be devoted to the discussion of topics and reading of papers upon subjects of vital importance to the industry, and it is believed that the programme as already outlined in the Western Electrician will attract many practical men who will be anxious to participate in the discussion. The arrangements for the entertainment of the visitors have been made with the view of allowing the members to attend each meeting of the association. In order that there might not be any inducement to members to remain away from the meetings, everything that would conflict with the order of business was eliminated. The ladies who will accompany the visiting members will be cared for during the day, and a special programme has been arranged for their benefit.

The tendency in the National Electric Light association is toward a strong, conservative and progressive organization that will exert a powerful influence, especially as an educational factor, in the community. The present administration is in hearty sympathy with this spirit, and the Chicago meeting will, it is hoped, serve as an example for future gatherings of the organization.

The announcement of the managers of the excursion-convention under the auspices of the Northwestern Electrical association proclaims the assurance of success, and all friends of the organization will welcome this cheering message. The novelty of the scheme is itself an attractive feature and should prove a drawing card, but there are other considerations which should insure a good attendance.

In many ways Mr. Insull's lecture at Purdue University on the "Development of the Central Station" is an exceedingly interesting and valuable contribution, and, as an historical document, it will doubtless be accepted generally as an authoritative statement of the claims of that "enthusiastic but small band of workers" mentioned in the address as "having an almost idolatrous belief in their chief as the pioneer of this great industry." It must be conceded, too, even by those who do not share the enthusiastic devotion that inspired this document throughout, that as Edison's historian Mr. Insull has very skillfully presented his claims, relying for evidence with which to support them almost entirely upon unfriendly witnesses. Mr. Insull's close association with Mr. Edison while the experimental work was being conducted, and the first central station at Pearl street, New York, was being built and equipped, afforded him exceptional facilities for gaining information bearing upon that important period and an opportunity to study the character of the directing genius in all these undertakings. It is not to be wondered, then, that a sketch of this kind by one so intimately identified with Mr. Edison should take on the character of a personal tribute. With these facts in mind we commend a careful perusal of Mr. Insull's lecture to all who are interested in the historical side of the electrical development of this country. The period covered in this address was probably the most interesting and undoubtedly the most important in the electric-lighting industry.

The wisdom of employing a competent attorney to prepare and present applications for patents should be universally recognized, yet there are many inventors who consider themselves the best advocates of their claims. It is evident that the new commissioner of patents intends to discourage the personal solicitation of patents by inventors who are not familiar with the requirements of the office. He has issued a circular calling attention to one feature, which, although comparatively unimportant, is nevertheless of enough moment to command consideration. The circular calls attention to order 789, dated November 26, 1892, which is as follows:

It is hereby directed that in the printing of claims of applications for patents the punctuation of the claims as made by applicants be strictly followed and that the punctuation of the specification made by applicants be not departed from except to cure a manifest absurdity.

This order is still in force, and the commissioner says: "Examiners are prohibited from making any change in the claims or specification of an application without the consent of applicants or their attorneys; but when amendment becomes necessary the office will duly advise, by letter, the applicant or his representative before passing a case to issue."

It might be added that this regulation applies with equal force to a certain class of solicitors, who have neither special knowledge nor experience and are not particularly well fitted for this class of work.

It has been proposed to utilize Röntgen rays in the hospitals of the American navy and army during the war with Spain, and it is encouraging to learn that their use in the Indian campaign saved life and useless mutilation. The London correspondent of the Sun says that the first reports of the use of the Röntgen rays in warfare was made on May 20th at the United Service Institution by Surgeon Beevor, who described the results of their use in the recent frontier campaign in India, and gave lantern views. Many important cases consisted of bullet wounds received by officers and men who were injured in bones, joints and internal organs. Their injuries, but for the X-rays, would have resulted in the amputation of limbs and probable loss of life. The pictures shown included wounds in the arm, leg, chest, back, finger and other parts. In every case the bullets were located by the use of the X-rays and successfully removed, the men subsequently rejoining their comrades at the front. The portable apparatus weighs 80 to 100 pounds. The subject is receiving attention at the hands of the army and navy surgeons, and similar devices will doubtless be adopted in the American service.

The right of a city council to grant an exclusive franchise to a street-railway company to occupy a public thoroughfare is denied by the Supreme Court of the United States. The question was raised in the case of the Detroit Citizens' Street Railway company against the Detroit Railway company and the city of Detroit, and the decision was handed down by Justice McKenna sustaining the ruling of the state courts of Michigan, from which appeal had been taken. In 1862 an ordinance was passed by the Detroit City Council giving to the Detroit City Railway company, of which the Detroit Citizens' company is the successor, the right to lay railways in streets voted by the council, to the exclusion of all other companies. In 1879 this right was extended for 30 years. In 1894 the council passed an ordinance giving the Detroit Railway company the right to lay tracks on the same streets already occupied by the lines of the old company. The latter brought suit at once to restrain the new organization, on the ground that the ordinance impaired the validity of its contract with the city. The decision is based upon the fact that public thoroughfares cannot be disposed of in the same manner as private property.

Those who favor the policy of municipalities assuming control of street-railway properties upon the expiration of the original franchises, or at any time designated in the ordinance granting the privileges, will be interested in the decision of the Court of Appeals denying the obligation of the Eighth Avenue Railroad company to surrender its railroad to the city of New York upon receiving in payment therefor an amount equal to the cost of the line and 10 per cent. additional. The grant to construct the road was made in 1851 to John Pettigrew and his associates by the Common Council, whose resolution required the grantees to stipulate to transfer the road to the city whenever required so to do upon payment of its cost and 10 per cent. thereon. The Court of Appeals declares this resolution to have been wholly void, because the Common Council thereby undertook to authorize the laying of railroad tracks in the city streets and avenues, a power which belonged not to that body, but to the Legislature. The contract made by Pettigrew and his associates in accordance with the terms of this void resolution is also held to have been void. In 1854, however, the Legislature passed an act relative to the construction of railroads in cities, which authorized those who had already commenced the building of such roads under municipal grants to complete them. This confirmed the rights of Pettigrew and his associates, which were subsequently acquired by the Eighth Avenue Railroad company. The decision will prove valuable to that corporation and to the Metropolitan Street Railway company, which has allied interests, and possibly to other companies operating under similar conditions.

WAR NEWS.

Chicago Edison Volunteers for Naval Service.—The group of portraits on this page depicts the features of former employes of the Chicago Edison company who tendered their services to the government on the first call for naval recruits and left Chicago on last Tuesday to join the squadron under Admiral Sampson. They are evidently well fitted for service, having passed very creditable examinations.

S. H. McEwen. J. Goldsmith.
W. B. Tullock. B. R. T. Collins. A. Montgomery.
T. Roberts.

CHICAGO EDISON VOLUNTEERS FOR NAVAL SERVICE.

B. R. T. Collins, who is the central figure in the group, was one of the most popular members of the engineering staff of the Chicago Edison company. He was graduated by the Massachusetts Institute of Technology in 1888, and for four years acted as instructor in that institution. He joined Sargent & Lundy during the construction of the Harrison street station of the Chicago Edison company, and upon the completion of that plant was induced to accept a position as assistant to the chief engineer, and conduct a series of exhaustive tests at the Harrison street power house, which have been carried to a point of completeness never before attempted in central-station practice. Mr. Collins was an active member of the Northwestern Alumni association of the Massachusetts Institute of Technology, and has occupied the office of president of that organization. He has kept abreast of the times, and attained an excellent reputation in engineering circles. He has always shown deep interest in naval affairs, and upon the organization of the naval reserves in this city, took an active part in the association. When the call for volunteers for the naval service was issued, Mr. Collins took the examinations prescribed by the government, together with 15 associate officers. He was eleventh in rank among the competitors, but stood third in the examination, and was appointed junior lieutenant. This excellent showing was particularly gratifying to Mr. Collins' friends, as several of the men who competed for honors were graduates of the naval academy at Annapolis.

The young men who accompany Mr. Collins were engaged in the Harrison and Washington street power plants of the Chicago Edison company. They all stood high in the examination for engineers, and expect to get good berths in consequence. They are S. H. McEwen, J. Goldsmith, W. B. Tullock, A. Montgomery and T. Roberts.

Cable Cutting at Cienfuegos.—Details of the tempt to cut the cables on the southern coast of Cuba by crews of the United States cruisers Nashville and Marblehead were presented in the Western Electrician last week. The picture on this page, which is reproduced through courtesy of the Chicago Record, shows the boats from the Nashville and Marblehead engaged in cutting the cables at Cienfuegos, under fire from the shore batteries. The picture was drawn by Schmedtgen, the Record's staff artist at the Key West rendezvous, from a sketch made by an officer on the Marblehead. The task of cutting the cables proved a very perilous undertaking, as the men were obliged to work in open boats, with no protection whatever from the fire of the enemy. According to the official report the men performed their work with the utmost coolness and intrepidity. The fire from the Maxim guns on shore and the infantry became too hot, however, and the crews were withdrawn, after sustaining a loss of two men killed and seven wounded. Two of the cables were cut at that time, and since then, it is said, the third was also found and severed.

GEN. A. W. GREELY.

General A. W. Greely.—The chief signal officer of the United States army, General Adolphus W. Greely, is one of the best known officers in the service, both at home and abroad. His expedition to the Arctic region gave him an international reputation and secured for him many honors from foreign scientific societies as well as promotion at home. The present war makes General Greely's position one of great importance. He has charge of the censorship which has been established over the war news sent from or received into this country by telegraph. He has established intimate relations with all the telegraph and cable companies to that end, and messages or parts of messages which are thought to be harmful to the interests of the government are not transmitted. The decision as to what is permissible is made by a number of censors, who are army officers, stationed at important points. In addition, the companies refuse to forward messages in secret or ambiguous language and generally co-operate with the authorities. The restric-

CABLE CUTTING AT CIENFUEGOS.—BOATS FROM THE NASHVILLE AND MARBLEHEAD UNDER FIRE FROM SHORE BATTERIES.

DEVELOPMENT OF THE TELEPHONE FIELD.

Telephone News from the Northwest.

(From the Minneapolis correspondent of the Western Electrician.)

The old officers and directors of the La Crosse (Wis.) Telephone company were all re-elected at the annual meeting.

The Central Telephone company has ordered material for an exchange to be established at Rockwell City, Ia.

The Iowa Telephone company is an applicant for a franchise into Primghar, Ia.

The Billings and Fergus County Telephone company has been incorporated to build a telephone line from Billings, Mont., to Lavina and later to Lewistown.

A telephone line has been completed between Butte, Mont., and Twin Bridges.

The Mount Ayr, Ia., telephone exchange is now a night office.

Agnes Hammontree, an employe of the Iowa Telephone company at Des Moines, sustained a severe accident while riding a bicycle. In a collision she was thrown to the pavement, striking on the back of her head and injuring the skull, it is feared, dangerously.

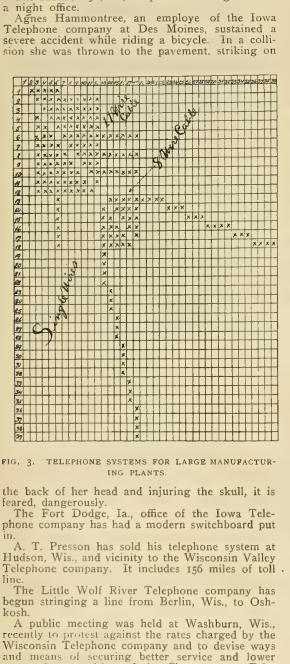

FIG. 3. TELEPHONE SYSTEMS FOR LARGE MANUFACTURING PLANTS.

The Fort Dodge, Ia., office of the Iowa Telephone company has had a modern switchboard put in.

A. T. Presson has sold his telephone system at Hudson, Wis., and vicinity to the Wisconsin Valley Telephone company. It includes 156 miles of toll line.

The Little Wolf River Telephone company has begun stringing a line from Berlin, Wis., to Oshkosh.

A public meeting was held at Washburn, Wis., recently to protest against the rates charged by the Wisconsin Telephone company and to devise ways and means of securing better service and lower rates. A proposition of the Chequamagon Telephone company to put in an exchange at a 25 per cent. reduction from present rates was accepted, and the system will be installed at once.

The Northwestern Telephone company has begun constructing a line between Elma and Charles City, Ia., and it will probably be continued to Cresco.

The Sioux Valley Electric and Telephone company has been incorporated at Arlington, S. D., with $50,000 capital stock.

The Minnesota Central Telephone company has about completed arrangements to establish an exchange for St. Cloud, Minn.

The Fergus Telephone company of Fergus Falls, Minn., has let the contract to Jones & Winter of St. Paul to install a telephone exchange. It is to be completed by July 31st.

The capital stock of the Mankato Citizens' Telephone company has been all paid up and 175 instruments taken on a five-year contract. Application will be made at once for a franchise to the council.

Manager Robinson has completed a telephone exchange at St. James, Minn., with about 60 instruments in use at the start.

The Marquette County Telephone company has been compelled to add another section to its switchboard at Ishpeming, Mich.

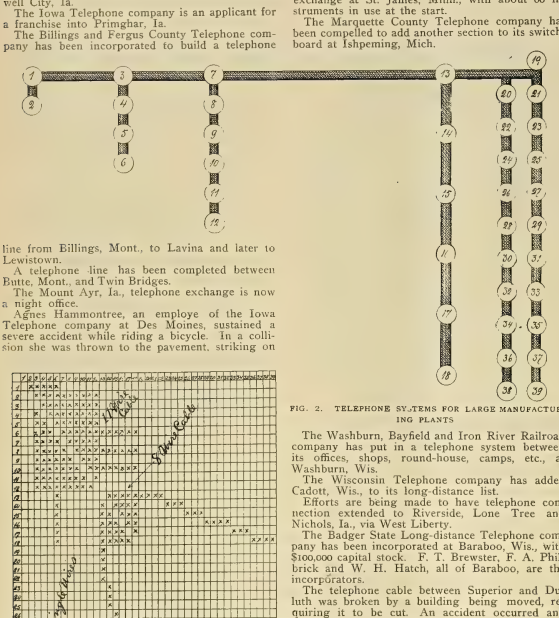

FIG. 2. TELEPHONE SYSTEMS FOR LARGE MANUFACTURING PLANTS

The Washburn, Bayfield and Iron River Railroad company has put in a telephone system between its offices, shops, round-house, camps, etc., at Washburn, Wis.

The Wisconsin Telephone company has added Cadott, Wis., to its long-distance list.

Efforts are being made to have telephone connection extended to Riverside, Lone Tree and Nichols, Ia., via West Liberty.

The Badger State Long-distance Telephone company has been incorporated at Baraboo, Wis., with $100,000 capital stock. F. T. Brewster, F. A. Philbrick and W. H. Hatch, all of Baraboo, are the incorporators.

The telephone cable between Superior and Duluth was broken by a building being moved, requiring it to be cut. An accident occurred and delayed the uniting of the break for some hours.

The Assembly of St. Paul has passed a franchise for the American Telephone and Telegraph company for a long-distance service in accordance with the company's request, but it stipulates that, in the event of the company establishing a local system, it shall not charge more than the lowest charge of any existing company, and gives the council authority to fix maximum rates.

The Luverne Telephone company will be formed at Luverne, Minn., to put in an exchange. Contracts have been closed for 65 instruments and a 100-drop switchboard has been ordered.

It is rumored the Iowa Telephone company will build through Adrian, Minn., this season.

Municipal Telephone Exchanges.

The great demand in England for municipal telephone exchanges may perhaps induce the government to grant licenses, says the London Electrical Engineer. At any rate the corporation must remember that the exchanges, if started, must be better and have more subscribers than those they compete with.

The postmaster-general has notified the highways committee of the London County Council, in reply to an application by that body for a license empowering the council to provide an independent municipal telephone service in London, that he feels it incumbent upon him to await the report of the select committee appointed by Parliament.

Telephone Systems for Large Manufacturing Plants.

By H. P. Clausen.

Since the advent of the telephone manufacturers independent of the American Bell Telephone company, thousands of telephone instruments have been sold to individual users, and, though widely differing opinions prevail regarding the probable total number of telephones already produced by the independent manufacturers, it may safely be assumed that at the present time the grand total is growing at the rate of at least 500 instruments per day.

In its simplest form the telephonic circuit consists of two telephones placed at the extremities of a connecting wire, and whenever telephone A desires to communicate with telephone B, the mere act of pressing a button, turning a crank or, more convenient still, removing the telephone receiver from its support, may be the means of calling the distant correspondent. As a matter of fact, such is indeed the ideal conception of a perfect telephone system—an unattainable condition, however, and we are therefore obliged to depend on some kind of a time-consuming means for interconnecting the circuits of three or more distinctly separate telephone systems.

We are all familiar with the service rendered by the average telephone companies, and that knowledge, in a way, is acting as a sort of a damper on the enthusiasm of managers for large manufacturing concerns, for whenever the question arises as to whether it would be advisable to install a local telephone system, the manager generally feels loath to add to his establishment that which appears to be a lot of complicated apparatus; but after once experiencing the immense savings of time that may be effected with a well-designed system properly installed, the wise manager never fails to speak a good word in favor of factory telephones.

Realizing the futility of attempting to give a general description of all systems designed especially for use in factories, etc., the writer will confine himself to the description of a most simple manually operated system, wherein all calling signals are transmitted by the caller direct; that is to say, he is able to create at will a temporary connection with the signal-receiving circuit of the desired correspondent. When it is necessary, however, to give service to a comparatively large number of stations operated on the plan mentioned, say over 20, the number of interconnecting wires that are required becomes rather large. Moreover, when it is considered that each wire belonging to a given telephone must be connected to every switching station of the system, it becomes quite plain why such systems are rarely employed in plants consisting of more than 20 stations.

Referring to Fig. 1, we have shown a system of 30 telephones connected on the usual plan. Allowing the questionable supposition that a common-return system would prove satisfactory, we must provide 30 switches, each having 30 points, making a total of 1,521 points. Now to connect the 30 switches to the 40-wire cable, it will be necessary to make in the neighborhood of 3,000 connections. To the telephone wireman 3,000 connections does not mean very much, but when it comes to putting so large a number of wire connections into a factory telephone system, where everything electrical must take care of itself, the 3,000 connections had better be cut down to one-tenth that number.

FIG. 1. TELEPHONE SYSTEMS FOR LARGE MANUFACTURING PLANTS.

In consideration of the fact that for factory purposes a direct-calling service is the nearest approach to the ideal—an individual line—which means, then, can we employ, which on following the same general plan, will give a satisfactory service, without introducing the objectionable features mentioned, that is, a large number of wires and possible points of trouble?

Referring to Fig 2, we have a diagrammatic rep-

resentation of the 39 telephone stations divided, according to the authority of their users, and in Fig. 3 a method is shown for sub-dividing the stations into communicating districts.

Referring to station No. 1, which corresponds to a telephone in the president's office, we find that this station may call any of the executive officers to their respective instruments, and that the No. 1 telephone cannot be called from any telephone in the entire system. The telephone in the general manger's office (No. 2), it will be observed, can be called only from the president's station, but the general manager is able to call any station excepting those that are under the direct charge of the general superintendent. The next district is composed of 10 stations belonging to the office proper, in which every individual user is able to communicate with any station belonging to his own district. An exception is made, however, in three stations, namely, the general superintendent, the purchasing agent and the shipping department, the general superintendent being able to signal and receive signals from any one of the six department superintendents, A, B, C, D, E and F. The purchasing agent and shipping department, though they cannot be called by any of the department superintendents, can at any time place their instruments in communication with those belonging to the department superintendents. The absence of local intercommunicative switching appliances also precludes the possibility of a workman entering into telephonic communication with any telephone station outside of that which is controlled by his chief, the department superintendent.

Referring once more to Fig. 3, it will be noted that the department superintendents are able to communicate with one another, the general superintendent and all such telephones as are placed throughout the factory and directly under their charge.

We have now arrived at another point, that is, the stringing of wires and placing of telephones in all parts of the factory proper. Nothing is liable to create more difficulties than the constant abuse to which such wires and instruments are subjected. The class of workmen employed in many large manufacturing plants will not permit the installing of any apparatus requiring special instructions for operation; therefore the instruments employed should be free from any form of plug or lever switches outside of such as are controlled by the receiver-supporting lever.

Now on having completed a general division of

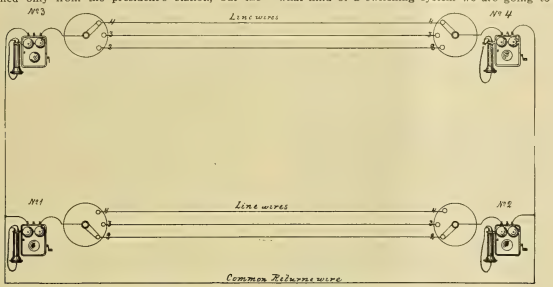

FIG. 4. TELEPHONE SYSTEMS FOR LARGE MANUFACTURING PLANTS.

It is not the object of this article to give any special recommendations as to the kind of instruments or switching appliances that should be employed. However, a few practical hints might be of value, and perhaps serve as a guide to the prospective investor.

Assuming that the division of telephone stations has been accomplished on the plan outlined in Fig. 3, and that the wirework is being installed by competent workmen, we have arrived at the point where it becomes necessary to decide what kind of a switching system we are going to adopt. As a basis for our consideration let us select the style of intercommunicating switch shown by Fig. 4, which in fact is the most widely known and simplest type yet produced. The system consists merely of a many-pointed single-lever switch. The line wires are connected one each to the points 1, 2, 3, etc. The local telephone is connected by one terminal to the switchlever and the other to a somewhat larger wire which connects to one terminal of every telephone in the system. The common wire must needs be somewhat larger than the individual wires, by reason of the interference that might ensue while two telephones, say No. 1 and No. 2, are in a conversational connection, and a third instrument, No. 3, is being operated for the purpose of signaling the telephone No. 4. As will be observed, the signaling current passes from the No. 3 generator through the line wire and through the signal receiver of telephone No. 4 and then back to its source at telephone No. 3; that is, it is supposed to take this course. However, if the common-return wire is not sufficiently large, a part of the signaling current may find an additional path through the telephones Nos. 2 and 1, but produce therein a disturbing influence, which, as a rule, is not had if the common wire offers a proportionally low-resistance return path.

When all switches are in a normal position, that is, if no telephone is in use, the switch levers are supposed to have been placed on the numbered switch point corresponding to the station number, for if this were not done any station having the switch lever on a point not corresponding with its own number could not be called unless, perchance, the station on whose point the lever rests were called, which, of course, would result in a false signal for the first-mentioned station. Regarding the contingency mentioned, several manufacturers have brought out a device whereby the replacing of a telephone receiver on its support tends always to restore the local signal receiver to its proper

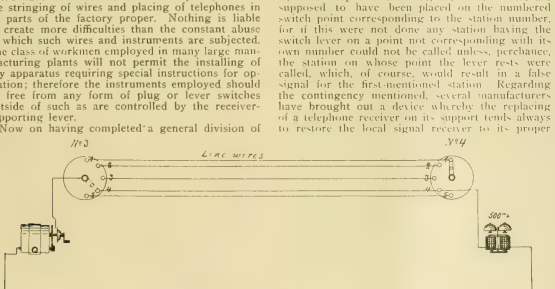

FIG. 5. TELEPHONE SYSTEMS FOR LARGE MANUFACTURING PLANTS.

a cord and plug. With this type of apparatus and the signal receiver (possessing a high retarding effect to the voice currents) connected, as shown in Fig. 5, it is hard to conceive how anything more simple can be devised.

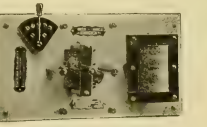
Having gone thus far we may as well go a little farther and give some consideration to the most vital objections to an intercommunicating system, where, with the simpler apparatus, it is possible for any telephone to interrupt or otherwise interfere with stations already in communication with one another. Although a large number of devices, both mechanical and electrical, have been designed for obviating the difficulty, it has been at the expense of simplicity.

The writer's intimate connection with designers of intercommunicating systems has impressed him with the idea that many designers of such systems make the most serious mistake of taking for granted that a particular feature in telephone instruments, if found objectionable in a given system, must be considered as objectionable if employed in connection with any other kind of a system. This point is quite apparent when we examine instruments intended for a small office system, wherein an absolutely non-interfering service must be rendered on the manually operated plan. The instruments devised for such service are numerous, and there are many intricate pieces of apparatus contained therein. Although such instruments are not really automatic, they certainly belong to that class, and should be treated as such when submitted for consideration.

A Battery Telephone Generator.

A novel machine, designed for telephone-exchange use, which can be operated by batteries as well as the electric-light current, and has ample capacity for exchanges of less than 1,200 instruments, is being introduced by the W. F. Warner company of Muncie, Ind. The power required to operate the machine is about 0.3 ampere at eight volts.

Many telephone exchanges throughout the country do not have access to lighting circuits, and many large exchanges have been compelled to use the hand generator, owing to the fact that they had no means to operate a separate or power generator. The cut herewith presented illustrates the new device.



A BATTERY TELEPHONE GENERATOR.

Extensions and Improvements.

The commercial telephone line between Lexington, Va., and Staunton has been completed.

The Janesville, Wis., Telephone company has been incorporated with a capital stock of $25,000.

The Eastern Illinois Telephone company of Kankakee, Ill., has increased its capital stock from $15,000 to $25,000.

The Village Council of Imlay City, Mich., has granted a 30-year franchise to the New State Telephone company.

The Northwestern Telephone company has been incorporated at Rush City, Minn., with a capital stock of $50,000.

E. W. Coleman of Columbia, Tenn., has applied to the City Council of Chattanooga, Tenn., for a telephone franchise.

A telephone line is contemplated connecting Albion, Ore., with Oakley, Minidoka and Kelton, and ultimately with Ogden.

Telephone communication between St. Louis and Kansas City and Topeka will soon be established by an "independent" line, it is said.

The Liberty, N. Y., Telephone company has sold its franchise, poles, wires and other property to the Delaware River Telephone company.

The New York and New Jersey Telephone company has established a station at the state camp at Sea Girt which gives direct communication with New Jersey's volunteers.

The plans for the new long-distance telephone company of Indianapolis provide for the building of a toll line through Anderson from Indianapolis to Muncie and Fort Wayne, connecting every city in Indiana.

The Central Union Telephone company has absorbed the Tom A. Marshall Telephone company, operating in Mercer and adjoining counties, and will immediately introduce a metallic circuit. The line will soon be extended to Galva, Ill.

The Fort Collins, Colo., telephone system is about to be extended to Livermore, a distance of 25 miles. The line will connect with La Porte and Bellevue and will be constructed conjointly by the citizens of Livermore and the Colorado Telephone company.

New York Electrical Exhibition.

Three characteristic exhibits at the New York electrical exhibition in Madison Square Garden are illustrated herewith. One is that of the Diesel Motor company of America. The picture shows a 20 horse power Diesel motor coupled directly by a rigid coupling to the armature shaft of a C & C generator. The motor was not built for electrical work, but is an ordinary 20 horse power stationary

NEW YORK ELECTRICAL EXHIBITION.—EXHIBIT OF SILEX INSULATION.

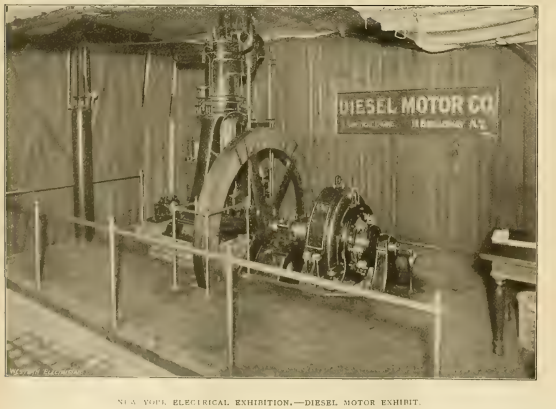
motor intended to run machinery by belt drive. It runs at only 170 revolutions per minute, is a single-cylinder motor and, like all internal-combustion motors, works on the four-stroke cycle. Time was not available to change the gearing for higher speed, desirable as that appeared for electrical work. It seemed therefore a bold undertaking to attempt to make it drive an electric-light generator. But public interest in the Diesel motor has been so aroused, and the opportunity to exhibit it at the Electrical exposition seemed so favorable, and, above all, the directors of the company have such absolute faith in the motor, that it was determined to exhibit it even under these adverse conditions. Delays in shipment and in the custom-house reduced the time for preparation. The only change that could be made in the time available was to supply the engine with a somewhat heavier flywheel than necessary for its ordinary work, and after two days of preparatory run it was set up in the exposition and carries its load of lights with less than 1½ per cent. variation. It requires less than a minute to start the engine when perfectly cold, and within two minutes it is running at full speed with its dynamo. It is believed that this is the first instance on record where a single-cylinder internal-combustion engine has ever accomplished these results. Those who have studied the working of the Diesel motor find the reason for this success in its controlled and perfect combustion and the absence of any explosive action.

The Silex Insulation company, 39-41 Cortlandt street, New York city, in its exhibit, shows a conduit constructed on a new principle of insulation. The conduit consists of an inner and outer tube, silex being packed between the tubes. This mineral, when pulverized, has no round particles in it; they are all sharp, angular, wedge-shaped, splintery. This enables it to be packed to a solidity approaching that of the rock from which it is ground. Thus, when the silex is packed, it forms an arch around the inner tube, so that it is impossible to decentralize the inner tube. Silex will not conduct heat or electricity, nor will it burn or melt. It is absolutely unchangeable. The "three-eye" conduit has at the ends mica wads, both receding and protruding, so that when these ends are connected up with a right and left coupler the insulation is completely continuous. The inner tube is a smooth metal tube; rubber-covered copper wire can be burned and melted out of it without affecting the conduit. The principle on which this conduit is made is the introduction of insulating materials, the particles of which are free to move relatively, which is the property of the flexible mineral insulator.

The Faries Manufacturing company of Decatur, Ill., manufacturer of the Faries universal adjustable electric-lamp holders, aluminum and steel electric lamp shades, and fire and water-tube boiler cleaners, has recently established an eastern office at 136 Liberty street, New York city, under the manage-

NEW YORK ELECTRICAL EXHIBITION.—FARIES COMPANY'S SPECIALTIES.

ment of A. W. Koenig, and it requests its patrons in the eastern states to send their inquiries and orders to this office, in order to save time and expense in shipping. Mr. Koenig has arranged a neat, attractive and interesting exhibit at the electrical show. The exhibit is located on the promenade just above the main floor, adjoining the new York Telephone company's theatrophone exhibit. Some of the holders are adjustable in four or five places, so that it is very easy to arrange them to throw the light anywhere that is desired by merely adjusting the fixture at the angle necessary. These fixtures are made in about 30 different designs of portable and stationary desk and table lamps, side-wall fixtures, chandeliers, pendant hall lamps and dental lamps. They are all very unique and attractive in design, while not at all elaborate, thus making the cost reasonable. The aluminum and steel shades or reflectors are made in three styles—the parabola or half shade, the cone-shaped and the ceiling shade. They are not only shades but reflectors. The holder reaches well over the shank of the lamp, leaving the shade to begin at the top of the filament, thus enabling a smaller shade of the same angle to cover the lamp as well as a larger one with the old style of holder. The advantage of the fire and water-tube boiler cleaner manufactured by this company is that it expands when shoved forward in the tube and collapses when pulled backward, so that it will never get stuck. It is easily adjusted for variations in sizes of tubes and has a ram which enhances the facility of operation, especially when tight and uneven places in the tubes are encountered. There is no leather or rubber about the cleaner, and it does the entire work without the use of steam or water.

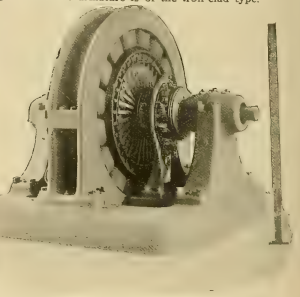


NEW YORK ELECTRICAL EXHIBITION.—DIESEL MOTOR EXHIBIT.

Large Rotary Transformer.

In the station of the Pennsylvania Heat, Light and Power company, Philadelphia, Pa., has recently been installed by the General Electric company the largest 60-cycle rotary transformer yet constructed. It is a 16-pole machine, of 400 kilowatts capacity, running at 450 revolutions per minute, and was designed to convert an alternating two-phase current of 60-cycles frequency and voltage variable between 165 and 220 volts into continuous current at from 225 to 300 volts. It is designated QC 16-400-450, and stands eight feet high on a base eight feet four inches by eight feet six inches.

The field frame of this machine is heavily ribbed, divided horizontally and susceptible of movement along the base to allow of inspection of the armature and field coils. The bearings are extra long and of the "G E" self-oiling and self-aligning type; that at the commutator end of the shaft is provided with an end-play device to keep the armature in constant motion in the direction of the length of the shaft and distribute the wear of the brushes over the commutator surface to avoid the wearing of grooves. The armature is of the iron-clad type.



LARGE ROTARY TRANSFORMER.

The commutator, carried on a separate spider, is of very ample surface and has a large number of segments. To facilitate the removal of a brush for examination and replacement without varying the tension under which it runs, a brush-holder of unique design has been devised. To remove the brush the prolonged end of the brush-holder spring is disengaged from the brush-holder by a slight end motion.

Another valuable feature in this machine is the design of the brush-holder studs and the method of attaching them to the yoke. The former, instead of passing through insulating bushings in the yoke—as has been customary in this type of machine—is provided with a lug bored to fit down upon a radial stud held by bolts passing through the insulating bushings. To slide the brush-holder stud off, it is simply necessary to loosen the nuts on the bolts passing through the bushings.

The cut shows the two-phase side of the converter. Upon the collector rings press numerous leaf brushes, having a long contact on the rings and a large current-carrying capacity.

To obtain the necessary variation in the continuous current of the rotary converter, the manufacturing company has furnished with it two special 60-cycle stationary transformers, each of 220 kilowatts capacity. These have been designed to operate with a primary potential of 2,000 volts and a secondary potential varying from 165 to 220 volts. The variation is obtained through a dial switch, over which passes a contact plate, cutting out or throwing in more or less turns of the primary winding and thereby varying the secondary potential. The switch is operated by a wheel handle, and the potential may be varied rapidly in either direction, the contact plate snapping from contact to contact in one direction as well as in the other. The dial switch is applied to the transformer itself instead of being a separate device, and the entire construction is singularly compact.

Chicago Electrical Association.

The members of the Chicago Electrical association had a fine time at the annual dinner of the society, which was held in the building of the Technical Club on the evening of May 20th. W. Clyde Jones was toastmaster, and the set toasts were as follows: "A Glance Into the Past," George Cutter; "The Power of the Press," Cloyd Marshall; "Tribu-

lations of the Electrical Inventor," K. B. Miller; "The Evolution of a Dynamo," E. P. Warner; "Specializing," Albert Scheible; "Electricity in Warfare," C. C. Mattison; "Shop Talk," Thomas E. Grier; "A Glance Into the Future," S. G. McMeen. An interesting informal discussion brought out the views of the members on the existing methods of the United States Patent Office.

The banquet committee in charge of this very successful dinner was J. M. Hollister, Albert Scheible and E. W. Jewell. The association has now over 50 members and is prosperous and vigorous.

National Electric Light Association.

The general reception committee, representing the electrical interests of Chicago, held another meeting on Monday afternoon for the purpose of considering the report of the sub-committee which had been instructed to complete arrangements for the entertainment of the visiting delegates to the convention of the National Electric Light association.

It was announced that the arrangements for the reception at the Auditorium on Monday evening, June 6th, had been completed. The reception will be held in the parlors of the hotel and light refreshments will be served. Music will be furnished and an excellent opportunity afforded the visitors to meet local electrical men. The reception will last from 8:30 until 10 p. m.

It was also proposed to have a ride on the lake, and Tuesday evening was selected for this entertainment. The committee was instructed to charter a steamer and make arrangements for music and refreshments for the same.

On Wednesday evening it was agreed to have a lecture by Joseph Wetzler of New York on "Electricity from Coal." It was thought that this would prove highly interesting to the general public as well as to the members of the association.

In order that the ladies of the party may not be left entirely to their own devices during the sessions of the convention, it has been proposed to give two tally-ho parties, one on Tuesday through the South Park system, to be followed by a luncheon, and another on Wednesday through the North Shore drive, Lincoln Park and the Sheridan drive. It is probable that the party may go through Buena Park and as far north as Evanston, provided the weather is favorable. It is anticipated that these drives will prove very attractive to the ladies.

President Insull has received many personal assurances from central-station managers that they will attend the Chicago meeting. He has addressed personal letters to many of his friends in the business, and hopes that this year's convention will be noteworthy by reason of the large attendance of central-station men.

As an accommodation to members the local committee has agreed to arrange for hotel accommodations for those who wish to have rooms secured in advance of the meeting. Mr. C. H. Wilmerding is the chairman of the committee.

Northwestern Electrical Association.

The Northwestern Electrical association has perfected its arrangements for the summer convention to be held on the steamer Northwest, leaving Chicago June 10th.

A meeting was held in Chicago Tuesday, May 24th, at the office of J. M. Hill, at which President Copeland, Pliny Norcross, E. L. Debell, W. W. Low, William Goltz and P. H. Korst were present.

Mr. Hill returned from an eastern trip on Sunday, and is enthusiastic over the prospects of a large number of central-station men being present. He has assurances that Mr. Edison, Professor Thomson, Mr. Sprague and Mr. Wood will attend, and that Mr. Stanley will also accept the invitation of the association. Mr. Brush, it is feared, will hardly be able to attend, although he commended the plan and said that if there was any possible way for him to leave his present work he would like to go.

The programme will consist principally of discussions. A feature of the programme will be the "question box." Those who do not desire to ask questions during the sessions can do so without revealing their identity.

It is expected that a paper on "Measuring Instruments" will be read by Mr. Edward Weston. A paper on the "Electrical Smelting of Ores," which is of such vital importance to the Lake Superior district, and which has so interested Mr. Pliny Norcross and Professor Thomson, will be read by W. S. Horry, the electrical engineer who constructed the furnaces for the Union Carbide company at Sault Ste. Marie.

Central-station men show a decided interest in this convention and express their desire to go. While the plan is a novel one, there is an opportunity for greater good to owners and managers of electric-light and power companies than has ever yet been afforded by a convention.

The matter of expense has been in some cases misunder-stood. There will be plenty of entertainment furnished by the steamer committee as well as by the citizens of the Soo, and the harbor of West Superior is to be one of the most elaborate events of its kind in the West.

State-room assignments are to be made at once, and, where ladies accompany members, it is important, that quick notice be given the chairman of arrangements, J. M. Hill, 1240 Monadnock block, Chicago, as it is desired that they shall be especially well taken care of.

Commonwealth Electric Company.

The policy of consolidation and absorption adopted by the Chicago Edison company some time ago has resulted in that company securing practical control of the electric-lighting industry in Chicago. The Commonwealth ordinance was the last measure of its kind passed by the City Council, and it is said to be the best working ordinance that has ever been granted in this city. The franchise is for 50 years from June 28, 1897, and it is proposed to organize all the small companies controlled by the Chicago Edison company under this ordinance. This will be a mere formality so far as the service is concerned, as the group of properties to be formally taken over in Hyde Park consists of the People's Light and Power company, the People's Electric Light and Motor Power company, the Hyde Park Thomson-Houston Electric Light company, the Englewood Electric Light and Power company, the Hyde Park Electric Light and Power company and the Mutual Electric Light and Power company, which have been controlled by the friends of the Edison company. The Commonwealth company has already taken formal possession of the West Chicago Electric Light and Power company which has been operating a station on West Madison street. The Western Light and Power company in Lake View will also be included in the combination. The Commonwealth will do its first business on the West Side, using for a time the plant on Madison street, but shortly the current will be obtained from the new station in the street.

When the details have been arranged there will be four going concerns in the outside territory, one station of the Hyde Park Thomson-Houston company, and two additional stations on the South Side, with the Western Light and Power company in Lake View. The change in management will dispense with five stations, three on the South, one on the West, and one on the North Side. Eventually the North Side station in Lake View will be one.

It will be realized at once that the Commonwealth will operate over an extremely large territory, as it will do the electric-lighting business outside the district bounded on the north by North avenue, on the west by Ashland avenue, and on the south by Thirty-ninth street, the present limits of the Chicago Edison company's territory. The new concern will occupy all the territory in which its franchises permits it to operate overhead wires, being bound by the following limits: North avenue from the lake west to Wells street, south along Wells street to Lake street, west along Lake to Ashland avenue, south along Ashland to Sixteenth street, east along Sixteenth street to Butterfield, south along Butterfield to Fifty-fifth street, and east along Fifty-fifth street to the lake.

The gross revenue from the electric-lighting business in the outside territory is between $450,000 and $500,000 per annum, but this is largely an arc-light service, and the Commonwealth company will develop incandescent service.

In order to accomplish the changes, extensions and improvements contemplated it is proposed to issue securities of the Commonwealth company aggregating $5,500,000, including 45-year five per cent. bonds for $2,500,000 and stock amounting to $3,000,000. These issues will be placed upon properties estimated to be worth double the bonds of the Chicago Edison company. The bonds will be put out for the purpose of covering, or capitalizing the cash investments made, and taking over finally the South Side group of electric properties. The organization of the company has been effected by the election of the following officers: President, Edward P. Russell; secretary and treasurer, Edward B. Burling.

This, it is believed, is merely a temporary arrangement, as it is understood that Mr Insull, who has been the guiding spirit in the enterprise, will be chosen president as soon as the corporation is well under way.

Western Society of Engineers.

On Saturday evening, May 21st, the Western Society of Engineers dedicated its new assembly room at 1741 Monadnock building, Chicago. About 175 gentlemen were present and passed an enjoyable evening. There was no formal programme, but Mr. W. J. Karner, the assistant engineer of the Illinois Central railroad, gave an interesting and timely description of his travels in Cuba, illustrated by many stereopticon pictures from photographs he had collected there. Refreshments were served, and good music enlivened the occasion.

The assembly room adjoins the society's library, which has nearly 3,000 books of engineering reference, and is well equipped for the purpose. It has a blackboard and screen for stereopticon views built in the wall back of the speaker's table. A Colt electric focusing lamp, mounted on a portable stand, is provided to project the lantern slide pictures or drawings used to illustrate the papers read before the society. This lamp is operated on a 110 volt lighting circuit, with suitable resistance, and the connection is made by a length of lamp cord giving the necessary radius of action, and a plug switch mounted on the lamp stand. A noticeable convenience is a push switch hanging by the speaker's table by which the lecturer can light or extinguish a shielded incandescent lamp in the back part of the room, thus signaling to the operator at the stereopticon when to change the picture on the screen.

Development of the Central Station.

[*Continued from page 309.*]

to provide for the economical production of steam, low cost of operating, good facilities for repairs and consequently low cost, and for permanency of service. You have but to go into any of the modern central stations in midwinter, to see them turning out anywhere from 10,000 to 30,000 amperes with a minimum of labor, to appreciate the fact that central-station business is of a permanent and lucrative character.

To go back to the question of alternating currents, the work done in connection with the two-phase and three-phase currents and the perfection of the rotary transformer has resulted in introducing into central-station practice a further means of economizing the cost of production—by concentration of power. Accepted present experience, it is (except in some extraordinary cases) uneconomical to distribute direct low-tension current over more than a radius of a mile and a half from the generating point. The possibility of transmitting it at a very high voltage, and consequently low investment in conductors, has resulted in the adoption of a scheme, in many of the large cities, of alternating transmission combined with low-tension distribution. The limit to which this alternating transmission can be economically carried has not yet been definitely settled, but it is quite possible even now to transmit economically from the center of any of our large cities to the distant suburbs, by means of high-potential alternating current, and distributing the current from the sub-center distribution by means either of the alternating current itself and large transformers for a block or district, or else, if the territory is thickly settled, by means of the present low-tension mains and feeders, the direct current for this purpose being obtained through the agency of rotary transformers.

There are various methods producing the alternating current for transmission purposes. In some cases the generators are themselves wound for high potential; in others they are wound for 80 volts, and step-up transformers are used, carrying the current up to whatever pressure is desired, from 1,000 to 10,000 volts. In other cases dynamos are used having collector rings for alternating current on one side and a commutator for direct current on the other side of the armature, thus enabling you, when the peak in two districts of a city comes at two different times of the day, as is the case by means of the same original generating unit, furnishing direct low-tension current to the points near the central station and alternating current to the distant points. In other cases, only a small amount of alternating current is required on the transmission line, it has even been found economical to take direct current from a large unit, change it by means of a rotary transformer into alternating current, step up from 80 to, say, 2,000 volts, go on the distant point, and step down again to 80 volts alternating, and then convert again by means of a rotary transformer into low-potential direct current.

The introduction of alternating current for transmission purposes has probably best exemplified in large cities in the station recently erected in Brooklyn, where alternating current is produced and carried to distant points, and then used to operate series arc-light machines run by synchronous motors, the low-tension direct-current network being fed by rotary transformers, and alternating circuits arranged with block converters, and even in some cases separate converters for each individual customer in the scattered districts.

It would be very interesting to go at length into the details of cost in this, the latest development of central-station transmission, but time will not permit, nor have I the time at my disposal to go at length into the central-station business as developed by the electric-street railways now so universally in use, or another phase of the business as exemplified by the large transmission plants, the two greatest examples of which in America are probably those at Niagara Falls, N. Y., and Lachine Rapids, near Montreal. So far as street railways and power transmission are concerned, I would draw your attention to the fact that the same underlying principle of multiple-arc mains and feeders originally conceived by Mr. Edison is as much a necessity in their operation as it is in the electric-lighting systems, whether those systems be operated on the old two-wire plan, the three-wire plan or by means of alternating currents.

Injunction in Street-railway Litigation.

A dispatch from New Haven, Conn., May 24th, says that Judge Townsend of the United States District Court handed down a decision in the case of the Electric Car company of America and the Thomson-Houston company against the Hartford and West Hartford Railroad company. The plaintiffs claimed an infringement of patent on a multiplying switch for electric motors. The decision orders an injunction and an accounting.

WAR NEWS.

[*Continued from page 311.*]

tion bears heavily upon the newspapers, but is patriotically accepted by press and public as a necessary evil. But the censorship is only a portion of the duties of the chief signal officer. General Greely supervises all the varied means of communication that are used by the land forces of the government. It was under his direction that the coast fortifications were inter-connected by telephone and telegraph; and the electrical connections with the submarine mines and torpedoes in the harbors were made by his expert subordinates. General Greely has charge, also, of the varied methods of field signaling, which will, of course, be of the greatest value in the military operations in Cuba and the Philippines. In short, the duties of the chief signal officer are multifarious, and he is required to be a man of the highest scientific attainments as well as a practical man of affairs.

General Greely was born in Massachusetts in 1844. He served in the army during the Civil War, enlisting as a private and rising to the rank of brevet major of volunteers in 1865. He has remained in the army ever since, and since 1868 he has been connected with the Signal Service. In 1881 he was sent to the Arctic regions to establish a scientific station, in accordance with a plan made by the Hamburg International Congress of 1879. On the return voyage in 1883 16 of the party perished by starvation, the survivors being rescued by a relief expedition. In 1886 the explorer published an account of his expedition, "Three Years of Arctic Service," in two volumes. This work was highly praised, both as a narrative and for scientific importance. General Greely attained his present rank of brigadier-general in 1887, when he succeeded General Hazen as chief ofthe Signal Service Corps. Since that time he has published a volume on "American Weather" and he has busied himself in perfecting his branch of the service. His persistent appeals to Congress for funds to equip lines of communication for the coast defenses are well known.

The portrait herewith given was made from a drawing prepared for the Chicago Times-Herald and kindly loaned to the Western Electrician.

Cable Restrictions.—The agreement between General Greely, representing the government, and the six cable companies having lines radiating from the United States, is said to be as follows:

In order to safeguard the public interests until further instructions, these companies refuse to receive or transmit the following:

First—Any and all messages, either to or from officials of Spain or any of her colonies, except such as are addressed to or signed by the president of the United States or any member of his cabinet in Washington city.

Second—All code or cipher messages to any point in the West Indies, Brazil or Venezuela, with the following exceptions:

(a) Messages addressed to or signed by the president or members of his cabinet at Washington.

(b) Messages exchanged between any ambassador or minister of Austria-Hungary, France, Germany, Great Britain, Italy and Russia in Washington city, and their duly recognized consular officials.

(c) Messages exchanged by neutral European governments and their consular agents, provided that such messages are officially signed and addressed.

Third—All messages in plain or open text that on their face contain information against the United States in the present war with Spain.

In addition to these general restrictions, the cable companies at Key West, Fla., and the Haytian Cable company, in New York city, decline to receive or forward any messages communicating information as to the movements of United States naval vessels or current military operations.

The United States has officially expressed its disinclination to exercise further military control or government supervision over the business of any of these telegraph cables than the necessities of the war will permit. It has expressly made known its preference that the companies shall have exclusive control over their own cables. To this end the United States has accepted the formal agreements of the presidents or authorized agents of these cable companies, given in writing, that they will neither receive nor transmit messages forbidden by the foregoing restrictions. It is recognized that these companies cannot exercise an exhaustive censorship over all messages in plain or open text, but it is expected that they will especially refrain from transmitting information as to the movements of naval vessels or current military operations.

The United States has expressed its desire to interfere to the least possible extent with the receipt or transmission of commercial messages.

More Cable Cutting Reported.—The Washington correspondents report that on May 24th the Navy Department issued this official statement: "The United States steamship St. Louis has cut the cable at Santiago de Cuba and San Juan de Porto Rico." This information is indefinite, as there are three cables landing at Santiago—one going west to Cienfuegos, another south to Jamaica, and the third east to Guantanamo and thence to Hayti. Both the eastern and southern outlets connect with transatlantic lines, so that it is still doubtful whether communication by cable between Spain and Cuba has been interrupted. There is little doubt, however, that the American naval officers are endeavoring to isolate Cuba, telegraphically and otherwise, and that the result will be accomplished.

Cable Repairs in War Time.—The English press, lay and technical, is watching the development of the present war closely for information. One lesson, drawn by the London Electrician, is worthy of attention. "In view of the enormous importance of cable communication in time of serious naval war," says this journal, "we are glad to learn that our Admiralty has already made provision that some of the officers should understand cable working and be in possession of the necessary appliances. In fact, on many of our battleships there are men who can send and receive Morse and mirror signals; but, in view of the suddenness with which war might arise, would it not be desirable to offer some inducement to secure that there should be men with every squadron who would understand something of the repair and testing of submarine lines? A fleet which could pick up a cable in mid-ocean and transmit or receive instructions for concentration, etc., as well as effect cable repairs, would surely have its offensive and defensive power greatly increased. We all know how for a time Villeneuve eluded Nelson before Trafalgar by doubling back from the West Indies; and in modern warfare the ability to pick up and work a cable might decide the fate of a great battle or even of a nation. The public is beginning to realize what has long been clear to experts, that coaling stations and bases for repairs are only second in importance to fleets and armaments of the latest type; but in addition to these the empire possesses a valuable resource, not only in the submarine lines, but also in the presence of British cable ships, with cable on board, and store cable tanks in various parts of the world. It is probable, in certain cases, that our fleets in war time will in the future be accompanied by a cable ship or ships of greater carrying capacity and higher speed than is necessary for the ordinary operations of vessels of this class. If the occasion should arise, we venture to think it will be found that those responsible have devoted much quiet thought and work to some of the problems which might arise—contingencies which should be of serious importance to a belligerent."

The Role of Electricity.—In responding to the toast "Electricity in Warfare," at the recent dinner of the Chicago Electrical association, C. C. Mattison, electrician of the Chicago Shipbuilding company, said, among other things: "Electricity has an important place both in land and naval operations. At night the electric searchlights and signal lanterns are indispensable. The searchlight in skillful hands sweeps the surrounding water, thus minimizing the danger of night attacks from torpedo boats. The signal lantern flashes its messages with even more distinctness than the flag in daytime. In a coast defense fort which a hostile fleet is approaching a call to quarters does not mean manning ramparts with guns exposed to the fire of the enemy, but the officer sits in the protected observing tower and operates his range-finder with awful accuracy. Electricity carries the ammunition, revolves the gun turret and finds the enemy. Electricity has made it necessary that the sailors be men of intellect. Science has robbed the tar of his picturesqueness, yet it has given us a man of nobler aspirations and intelligence."

Telephotos for the Buffalo.—The Boughton Telephotos company of Buffalo has decided to equip the new cruiser Buffalo with a full set of telephotos instruments especially prepared for her, because of her name. In accordance with this decision the company wrote to Washington to learn if the gift would be acceptable and received a satisfactory response. This decision was naturally highly gratifying to the company, and a special set of instruments will be at once prepared for the cruiser. While everything about their construction will conform to strict navy standards, every possible nicety of finish and furnishings will go with this special set, and the polished keyboard binnacle will bear a silver plate with this inscription:

This set of instruments
is presented to the
U. S. S. Buffalo
In honor of the name
it bears.

The value of the set will be $550, and it is certain that no matter what rush orders are received the cruiser Buffalo will be well cared for.
